IRONWOOD POST-PROJECT CONDITION HYDROLOGY
UNIT HYDROGRAPH ANALYSIS, 100-YEAR, 1-HOUR STORM DURATION
ONSITE AREA "A2"
FILENAME: ARA2ONSITE

Drainage Area = 23.24(Ac.) = 0.036 Sq. Mi.
Drainage Area for Depth-Area Areal Adjustment = 23.24(Ac.) = 0.036 Sq. Mi.
Length along longest watercourse = 1332.85(Ft.)
Length along longest watercourse measured to centroid = 1040.51(Ft.)
Length along longest watercourse = 0.252 Mi.
Length along longest watercourse measured to centroid = 0.197 Mi.
Difference in elevation = 45.90(Ft.)
Slope along watercourse = 181.8299 Ft./Mi.
Average Manning's 'N' = 0.015
Lag time = 0.043 Hr.
Lag time = 2.57 Min.
25% of lag time = 0.64 Min.
40% of lag time = 1.03 Min.
Unit time = 5.00 Min.
Duration of storm = 24 Hour(s)
User Entered Base Flow = 0.00(CFS)

2 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
23.24	2.00	46.48

100 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
23.24	5.00	116.20

STORM EVENT (YEAR) = 100.00
Area Averaged 2-Year Rainfall = 2.000(In)
Area Averaged 100-Year Rainfall = 5.000(In)

Point rain (area averaged) = 5.000(In)
Areal adjustment factor = 100.00 %
Adjusted average point rain = 5.000(In)

Sub-Area Data:

Area(Ac.)	Runoff Index	Impervious %
23.240	54.40	0.500

Total Area Entered = 23.24(Ac.)

RI AMC2	RI AMC-2	Infil. Rate (In/Hr)	Impervious (Dec.%)	Adj. Infil. Rate (In/Hr)	Area% (Dec.)	F (In/Hr)
54.4	54.4	0.527	0.500	0.290	1.000	0.290
					Sum (F) =	0.290

Area averaged mean soil loss (F) (In/Hr) = 0.290
Minimum soil loss rate ((In/Hr)) = 0.145
(for 24 hour storm duration)
Soil low loss rate (decimal) = 0.500

IRONWOOD POST-PROJECT CONDITION HYDROLOGY
UNIT HYDROGRAPH ANALYSIS, 100-YEAR, 1-HOUR STORM DURATION
ONSITE AREA "B"
FILENAME: ARBONSITE

Drainage Area = 15.65(Ac.) = 0.024 Sq. Mi.
Drainage Area for Depth-Area Areal Adjustment = 15.65(Ac.) = 0.024 Sq. Mi.
Length along longest watercourse = 1881.50(Ft.)
Length along longest watercourse measured to centroid = 959.32(Ft.)
Length along longest watercourse = 0.356 Mi.
Length along longest watercourse measured to centroid = 0.182 Mi.
Difference in elevation = 136.00(Ft.)
Slope along watercourse = 381.6529 Ft./Mi.
Average Manning's 'N' = 0.015
Lag time = 0.041 Hr.
Lag time = 2.47 Min.
25% of lag time = 0.62 Min.
40% of lag time = 0.99 Min.
Unit time = 5.00 Min.
Duration of storm = 6 Hour(s)
User Entered Base Flow = 0.00(CFS)

2 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
15.65	1.20	18.78

100 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
15.65	2.50	39.13

STORM EVENT (YEAR) = 100.00
Area Averaged 2-Year Rainfall = 1.200(In)
Area Averaged 100-Year Rainfall = 2.500(In)

Point rain (area averaged) = 2.500(In)
Areal adjustment factor = 99.99 %
Adjusted average point rain = 2.500(In)

Sub-Area Data:

Area(Ac.)	Runoff Index	Impervious %
15.650	68.90	0.429

Total Area Entered = 15.65(Ac.)

RI AMC2	RI AMC-2	Infil. Rate (In/Hr)	Impervious (Dec.%)	Adj. Infil. Rate (In/Hr)	Area% (Dec.)	F (In/Hr)
68.9	68.9	0.374	0.429	0.230	1.000	0.230
					Sum (F) =	0.230

Area averaged mean soil loss (F) (In/Hr) = 0.230
Minimum soil loss rate ((In/Hr)) = 0.115
(for 24 hour storm duration)
Soil low loss rate (decimal) = 0.557

APPENDIX E: STREET CAPACITY NORMAL DEPTH CALCULATIONS

APPENDIX E.1: 36' RIGHT-OF-WAY HALF-STREET TOP-OF-CURB CAPACITY

Rating Table for 36' ROW Street Section-Half Street TC

Project Description

Friction Method	Manning Formula
Solve For	Discharge

Input Data

Channel Slope	0.01750	ft/ft
Normal Depth	0.50	ft
Section Definitions		

Station (ft)	Elevation (ft)
0+00.000	0.50
0+00.125	0.00
0+02.125	0.17
0+02.125	0.20
0+18.000	0.52

Roughness Segment Definitions

Start Station	Ending Station	Roughness Coefficient
(0+00.000, 0.50)	(0+18.000, 0.52)	0.015

Channel Slope (ft/ft)	Discharge (ft³/s)	Velocity (ft/s)	Flow Area (ft²)	Wetted Perimeter (ft)	Top Width (ft)
0.00500	6.96	2.22	3.14	17.63	17.20
0.00600	7.63	2.43	3.14	17.63	17.20
0.00700	8.24	2.62	3.14	17.63	17.20
0.00800	8.81	2.80	3.14	17.63	17.20
0.00900	9.34	2.98	3.14	17.63	17.20
0.01000	9.85	3.14	3.14	17.63	17.20
0.01100	10.33	3.29	3.14	17.63	17.20
0.01200	10.79	3.44	3.14	17.63	17.20
0.01300	11.23	3.58	3.14	17.63	17.20

Rating Table for 36' ROW Street Section-Half Street TC

APPENDIX G.3: BIORETENTION BASIN SIZING SPREADSHEETS

Bioretention Facility - Design Procedure (Irregular Shaped Facility)	BMP ID: Basin A1	Legend:	Required Entries / Calculated Cells

Company Name:	JLC Engineering & Consulting	Date:	5/16/2016
Designed By:	Jilleen Ferris	County/City Case No.:	Ironwood

Design Volume

Enter the area tributary to this feature		$A_T =$	25.15	acres
Enter V_{BMP} determined from Section 2.1 of this Handbook		$V_{BMP} =$	23805	ft^3

Type of Bioretention Facility Design

(●) Irregular shaped with side slopes required (parallel to parking spaces or adjacent to walkways)

( ) Irregular shaped with no side slopes required (perpendicular to parking space or planter boxes)

Bioretention Facility Surface Area

Proposed Bottom Surface Area of Irregular Shaped Facility		$A_P =$	25518	ft^2
Depth of Soil Filter Media Layer		$d_S =$	3	ft
Total Volume within Soil Media, V_S	$V_S = (A_P * d_S * 0.3) + (A_P * 0.4)$	$V_S =$	33173.4	ft^3
Total Surcharge Storage Volume above Soil Media, V_P		$V_P =$	12759	ft^3
Total Effective Storage Volume, V_E	$V_E = V_S + V_P$	$V_E =$	45932.4	ft^3
Total Effective Depth, d_E	$d_E = \frac{V_E}{A_P}$	$d_E =$	1.80	ft
Minimum Surface Area, A_M	$A_M = \frac{V_{BMP}}{d_E}$	$A_M =$	13225	ft^2

Bioretention Facility Properties

Side Slopes in Bioretention Facility	z =	4	:1
Diameter of Underdrain		6	inches
Longitudinal Slope of Site (3% maximum)		0.001	%
6" Check Dam Spacing		0	feet

Describe Vegetation:

Notes: Basin side slopes include 50% at 2:1.

APPENDIX G.5: VOLUME SUMMARY TABLES FOR HYDROLOGIC CONDITIONS OF CONCERN

Area	Pre-Project 2-Year, 24-Hour Volume	Post-Project 2-Year, 24-Hour Volume	Basin Volume Provided
A1	0.4191 ac-ft	2.0957 ac-ft	3.0960 ac-ft
A2	0.4950 ac-ft	2.4749 ac-ft	7.9900 ac-ft [1]
B	0.2608 ac-ft	1.1560 ac-ft	7.9900 ac-ft [1]

1 - Area A2 and B will be mitigated within Basins A2 and B, which will function together for addressing the hydrologic conditions of concern and increased runoff mitigation. The total 2-year, 24-hour volume to both basins from Areas A2 and B is 3.6309 ac-ft, and the basin has a total available volume of 7.9900 ac-ft, therefore the basins have sufficient volume to address the hydrologic conditions of concern.

APPENDIX G.6: VOLUME SUMMARY TABLES FOR INCREASED RUNOFF MITIGATION

Basin A1 (Unit Hydrograph Summary)

	100-Year Storm Events			
	1-Hour	3-Hour	6-Hour	24-Hour
Onsite Flow Rate	41.6 ft^3/s	25.5 ft^3/s	21.8 ft^3/s	8.1 ft^3/s
Offsite Flow Rate	74.7 ft^3/s	44.0 ft^3/s	34.4 ft^3/s	16.2 ft^3/s
Allowable Offsite Flow-By	45.6 ft^3/s	45.6 ft^3/s	45.6 ft^3/s	45.6 ft^3/s
Onsite Volume Generated	1.3901 ac-ft	1.8294 ac-ft	2.2213 ac-ft	3.9417 ac-ft
Offsite Volume Generated	2.6284 ac-ft	3.5390 ac-ft	3.828 ac-ft	6.3263 ac-ft
Basin Storage Volume	3.0960 ac-ft	3.0960 ac-ft	3.0960 ac-ft	3.0960 ac-ft
Onsite Volume Retained [1]	1.3901 ac-ft	1.8294 ac-ft	2.2213 ac-ft	3.0960 ac-ft
Offsite Volume Retained [2]	1.3661 ac-ft	0 ac-ft	0 ac-ft	0 ac-ft
Total Volume Retained	2.7892 ac-ft	1.8294 ac-ft	2.2213 ac-ft	3.0960 ac-ft
Maximum Basin Outflow [3]	45.6 ft^3/s	44.0 ft^3/s	34.4 ft^3/s	21.7 ft^3/s

1 - The onsite volume retained equals the total onsite volume generated, with the exception of the 24-hour storm duration. This duration resulted in a larger volume than available to store within the basin, therefore a corresponding flow rate was calculated on the recess limb of the hydrograph where the calculations reached 3.0960 ac-ft of volume generated, equaling 5.5 cfs of outflow.

2 - The offsite volume retained for the basin was determined in the previous summary tables by taking the delta volume difference between the rising and recess limbs of the hydrograph where approximately 45.6 cfs occurs. The 3-hour, 6-hour and 24-hour durations have peak flows less than the 45.6 cfs allowable, therefore the entire flow rates for these durations will flow-by.

3 - The maximum basin outflow equals the maximum flow-by for the 1-hour storm duration, the peak flow rate for the 3-hour and 6-hour storm durations, and the peak offsite flow rate plus the Basin A1 onsite outflow of 5.5 cfs.

Basin A2 and Basin B (Unit Hydrograph Summary)

	100-Year Storm Events			
	1-Hour	3-Hour	6-Hour	24-Hour
Onsite Flow Rate [4]	96.7 ft^3/s	56.5 ft^3/s	48.4 ft^3/s	17.7 ft^3/s
Offsite Flow Rate	159.9 ft^3/s	98.6 ft^3/s	82.6 ft^3/s	36.0 ft^3/s
Allowable Offsite Flow-By	97.5 ft^3/s	97.5 ft^3/s	97.5 ft^3/s	97.5 ft^3/s
Onsite Volume Generated [4]	3.0274 ac-ft	3.9614 ac-ft	4.7718 ac-ft	8.4048 ac-ft
Offsite Volume Generated	6.0253 ac-ft	7.7868 ac-ft	8.0310 ac-ft	12.9052 ac-ft
Basin Storage Volume	7.9900 ac-ft	7.9900 ac-ft	7.9900 ac-ft	7.9900 ac-ft
Onsite Volume Retained [1]	3.0274 ac-ft	3.9614 ac-ft	4.7718 ac-ft	7.9900 ac-ft
Offsite Volume Retained [2]	3.1096 ac-ft	1.2671 ac-ft	0 ac-ft	0 ac-ft
Total Volume Retained	6.1370 ac-ft	5.2285 ac-ft	4.7718 ac-ft	7.9900 ac-ft
Maximum Basin Outflow [3]	97.5 ft^3/s	97.5 ft^3/s	82.6 ft^3/s	38.9 ft^3/s

1 - The onsite volume retained equals the total onsite volume generated, with the exception of the 24-hour storm duration. This duration resulted in a larger volume than available to store within the basin, therefore a corresponding flow rate was calculated on the recess limb of the hydrograph where the calculations reached 7.9900 ac-ft of volume generated, equaling 2.9 cfs of outflow.

2 - The offsite volume retained for the basin was determined in the previous summary tables by taking the delta volume difference between the rising and recess limbs of the hydrograph where approximately 97.5 cfs occurs. The 6-hour and 24-hour durations have peak flows less than the 97.5 cfs allowable, therefore the entire flow rates for these durations will flow-by.

3 - The maximum basin outflow equals the maximum flow-by for the 1-hour and 3-hour storm durations, the peak flow rate for the 6-hour storm duration, and the peak offsite flow rate plus the Basin A2 and Basin B onsite outflow of 2.9 cfs.

4 - The onsite flow rate and volume is equal to the summation of Onsite Area A1 and Onsite Area B flow rates and volumes.

Flow Title : ExistingCondition
Flow File : o:\150.06.14\Engineering\HEC-RAS\HEC-RAS Models\HEC-RAS Models-WSPG DS WSE\Existing Condition\ExistingCondition.f01

Plan Summary Information:

Number of:	Cross Sections	= 30	Multiple Openings	=	0
	Culverts	= 4	Inline Structures	=	0
	Bridges	= 0	Lateral Structures	=	0

Computational Information
Water surface calculation tolerance = 0.01
Critical depth calculation tolerance = 0.01

Maximum number of iterations = 20
Maximum difference tolerance = 0.3
Flow tolerance factor = 0.001

Computation Options
Critical depth computed only where necessary
Conveyance Calculation Method: At breaks in n values only
Friction Slope Method: Average Conveyance
Computational Flow Regime: Mixed Flow

Warning: During the culvert inlet control computations, the program could not balance the culvert/weir flow. The reported inlet energy grade answer may not be valid.
Note: The normal depth exceeds the height of the culvert. The program assumes that the normal depth is equal to the height of the culvert.
Note: Culvert critical depth exceeds the height of the culvert.

```

Note: During the supercritical calculations a hydraulic jump occurred at the outlet of (leaving) the culvert.
Warning: During the supercritical analysis, the program could not converge on a supercritical answer in the downstream cross
section. The program used the solution with the least error.
Note: During supercritical analysis, the culvert direct step method went to normal depth. The program then assumed normal
depth at the outlet.
Note: The flow in the culvert is entirely supercritical.

Warning: The flow through the culvert is supercritical.  However, since there is flow over the road (weir flow), the
program cannot
         determine if the downstream cross section should be subcritical or supercritical.  The program used the
downstream
         subcritical answer, even though it may not be valid.
Note:    The flow in the culvert is entirely supercritical.

Note: During the supercritical calculations a hydraulic jump occurred at the outlet of (leaving) the culvert.
Warning: During the supercritical analysis, the program could not converge on a supercritical answer in the downstream cross section. The program used the solution with the least error.
Note: The flow in the culvert is entirely supercritical.

Run Date and Time: 7/6/2016 3:58:12 PM

Project in English units

Project Description:
5.8HEC-RAS Project and Geometry created by SmartDraft

PLAN DATA

Plan Title: Post-Project
Plan File : o:\150.06.14\Engineering\HEC-RAS\HEC-RAS Models\HEC-RAS Models-WSPG DS WSE\Post-Project Condition\Post-Project.p02

Geometry Title: Post-Project
Geometry File : o:\150.06.14\Engineering\HEC-RAS\HEC-RAS Models\HEC-RAS Models-WSPG DS WSE\Post-Project Condition\Post-Project.g03

Flow Title   : Post-Project
Flow File   : o:\150.06.14\Engineering\HEC-RAS\HEC-RAS Models\HEC-RAS Models-WSPG DS WSE\Post-Project Condition\Post-Project.f02

Plan Summary Information:
```
Number of:  Cross Sections =   22    Multiple Openings  =    0
            Culverts       =    2    Inline Structures  =    0
            Bridges        =    0    Lateral Structures =    0
```

Computational Information
Water surface calculation tolerance = 0.01
Critical depth calculation tolerance = 0.01
Maximum number of iterations = 20
Maximum difference tolerance = 0.3
Flow tolerance factor = 0.001

Computation Options
Critical depth computed only where necessary
Conveyance Calculation Method: At breaks in n values only
Friction Slope Method: Average Conveyance
Computational Flow Regime: Mixed Flow

FLOW DATA

Flow Title: Post-Project
Flow File : o:\150.06.14\Engineering\HEC-RAS\HEC-RAS Models\HEC-RAS Models-WSPG DS WSE\Post-Project Condition\Post-Project.f02

Flow Data (cfs)

Warning: The flow through the culvert is supercritical.  However, since there is flow over the road (weir flow), the program
cannot
         determine if the downstream cross section should be subcritical or supercritical.  The program used the downstream
         subcritical answer, even though it may not be valid.
Note:    The flow in the culvert is entirely supercritical.

  Culv Crt Depth (ft)         2.24    Min El Weir Flow (ft)    1818.81

Note:    During the supercritical calculations a hydraulic jump occurred at the outlet of (leaving) the culvert.
Warning: During the supercritical analysis, the program could not converge on a supercritical answer in the downstream cross
         section.  The program used the solution with the least error.
Note:    The flow in the culvert is entirely supercritical.

GENERAL NOTES
1. Sanitary sewer shall be constructed to the Specifications of the Eastern Municipal Water District.
2. Power will be installed to the Specifications of the Southern California Edison Co.
3. Curb and Gutter, A.C. pavement, ect. will be installed to the Specifications of the Riverside County Road Dept.
4. All grading shall be done in accordance with the U.B.C. Chapter 70 as ammended by Riverside Grading Ordinance No. 457 and Preliminary soils report by S.E. Medall & Assoc, Inc. W.O. 1154 Dated May 16, 1978.
5. All shaded areas denote cut or fill banks having a maximun slope of 2:1.
6. Tranition lots (Daylight Lines). ( ) are to be undercut and recompacted to min. 90% density 12" below bottom of footings.
7. All grading shall be done under the supervision of a competent soils engineer who shall certify that all fill has been properly placed and who shall submit a final compaction report. The final compaction report shall include foundation design recommendations and certification that grading has been done in conformance with the recommendations of the Preliminary soils report.
8. A registered Civil Engineer shall submit to the building and safety Department, a written certification of completion of grading in accordance with the approved grading plan prior to issuance of the building permit.
9. No fill shall be placed on existing ground until the ground has been cleaned of weeds, debris, top soil, and other deleterious material.
10. Dust shall be controlled by watering.
11. Minimum building pad and drainage swale slope shall be 1%. Drainage swales shall be a min. of 0.3' deep and shall be constructed a min. of 2 feet from the top of Cut of fill slopes and property lines.
12. Cut slopes equal to or greater than 5' in vertical height and fill slopes equal to or greater than 3' in vertical height shall be planted with grass or ground cover to protect the slope from erosion and instability in accordance with Ordinance Number 457 prior to the approval of final inspection.
13. During rough grading operations and prior to construction of permanent drainage structures, temporary drainage control shall be provided to prevent ponding water and damage to adjacent properties.
QUANTITY ESTIMATE
FOR BID PURPOSES ONLY
CUT 42,700 C.Y.
These quantities do not include any over excavation that may be required by the soils report. The above quantities do not reflect subsidence, shrinkage or any other special conditions called for by the preliminary soils investigation.

MAP INFORMATION

The soil surveys that comprise your AOI were mapped at 1:15,800.

Please rely on the bar scale on each map sheet for map measurements.

Source of Map: Natural Resources Conservation Service
Web Soil Survey URL: http://websoilsurvey.nrcs.usda.gov
Coordinate System: Web Mercator (EPSG:3857)

Maps from the Web Soil Survey are based on the Web Mercator projection, which preserves direction and shape but distorts distance and area. A projection that preserves area, such as the Albers equal-area conic projection, should be used if more accurate calculations of distance or area are required.

This product is generated from the USDA-NRCS certified data as of the version date(s) listed below.

Soil Survey Area: Western Riverside Area, California
Survey Area Data: Version 7, Sep 17, 2014

Soil map units are labeled (as space allows) for map scales 1:50,000 or larger.

Date(s) aerial images were photographed: May 3, 2010—Jul 3, 2010

The orthophoto or other base map on which the soil lines were compiled and digitized probably differs from the background imagery displayed on these maps. As a result, some minor shifting of map unit boundaries may be evident.

Description

Hydrologic soil groups are based on estimates of runoff potential. Soils are assigned to one of four groups according to the rate of water infiltration when the soils are not protected by vegetation, are thoroughly wet, and receive precipitation from long-duration storms.

The soils in the United States are assigned to four groups (A, B, C, and D) and three dual classes (A/D, B/D, and C/D). The groups are defined as follows:

Group A. Soils having a high infiltration rate (low runoff potential) when thoroughly wet. These consist mainly of deep, well drained to excessively drained sands or gravelly sands. These soils have a high rate of water transmission.

Group B. Soils having a moderate infiltration rate when thoroughly wet. These consist chiefly of moderately deep or deep, moderately well drained or well drained soils that have moderately fine texture to moderately coarse texture. These soils have a moderate rate of water transmission.

Group C. Soils having a slow infiltration rate when thoroughly wet. These consist chiefly of soils having a layer that impedes the downward movement of water or soils of moderately fine texture or fine texture. These soils have a slow rate of water transmission.

Group D. Soils having a very slow infiltration rate (high runoff potential) when thoroughly wet. These consist chiefly of clays that have a high shrink-swell potential, soils that have a high water table, soils that have a claypan or clay layer at or near the surface, and soils that are shallow over nearly impervious material. These soils have a very slow rate of water transmission.

If a soil is assigned to a dual hydrologic group (A/D, B/D, or C/D), the first letter is for drained areas and the second is for undrained areas. Only the soils that in their natural condition are in group D are assigned to dual classes.

1.0 INTRODUCTION

1.1 Purpose

The purpose of this evaluation was to provide due diligence level preliminary geotechnical information to Anderson Consulting Engineers, Inc. ("Client"), regarding the subject property in the City of Moreno Valley, Riverside County, California. The information developed in this evaluation is intended to provide the Client with an understanding of the physical conditions of site-specific subsurface soils, groundwater, and the regional geologic setting which could affect the cost or design of the proposed development at the subject property (Site Vicinity Map-**Figure 1**, Aerial Site Map-**Figure 2**).

This Due Diligence Preliminary Geotechnical Evaluation has been conducted in general accordance with the accepted geotechnical engineering principles and in general conformance with the approved revised proposal and cost estimate for the project by EEI, dated September 23, 2014.

EEI conducted an onsite field exploration on October 16 and 17, 2014 that included excavation and sampling of four (4) exploratory backhoe trenches and drilling and sampling of four (4) hollow stem auger geotechnical borings for the proposed development at the subject property. Also, three (3) additional shallow borings were drilled to depths of 3 feet or less below the existing ground surface in the areas of proposed detention basins in order to perform field percolation testing. Three (3) additional hollow stem auger geotechnical borings were drilled and sampled for the proposed offsite sewer alignment located approximately ¼ mile south of the main subject property. This Due Diligence Preliminary Geotechnical Evaluation has been prepared for the sole use of Anderson Consulting Engineers, Inc. Other parties, without the express written consent of EEI and the Client should not rely upon this due diligence level preliminary geotechnical evaluation.

1.2 Project Description

We understand that the Client is considering purchasing the subject property for a residential project. Based on a Project Exhibit provided to EEI by Anderson Consulting Engineers, Inc., it appears that the subject property will be developed into approximately 146 residential building pads and associated streets and other improvements. A future offsite sewer extension is proposed for the right-of-way near the southern terminus of Oliver Street approximately ¼ mile south of the subject property. The approximate depth of the proposed sewer is about 25 feet below the existing ground surface within the Eastern Municipal Water District (EMWD) water main right-of-way. No further information is known at this time.

1.3 Scope of Services

The scope of our services included:

- A review of readily available data pertinent to the subject property, including published and unpublished geologic reports/maps, aerial photographs, local groundwater information, and soils data for the area (**References**).
- Conduct a geotechnical reconnaissance of the subject property and nearby vicinity.
- Coordinate with Underground Service Alert to identify the presence of underground utilities for clearance of proposed boring and test pit locations.

- The drilling and logging of four (4) hollow stem auger (HSA) borings (B-1 through B-4) throughout the subject property, ranging from 16 to 50.5 feet below existing grade elevations (bgs). One of the HSA exploratory borings was extended to 50.5 feet bgs for preliminary evaluation of settlement.

- The drilling and logging of three (3) additional hollow stem (HSA) auger borings (B-5 through B-7) in readily accessible areas along the proposed offsite sewer extension near the southern terminus of Oliver Street. The three (3) borings were extended to depths of approximately 26.5 feet below the existing ground surface along the approximate proposed sewer alignment

- Perform field percolation testing at three (3) locations (P-1 through P-3) at depths of approximately 3 feet below the existing ground surface at the locations of proposed detention basins as shown on the Project Exhibit. Testing was performed in general accordance with the County of Riverside guidelines for percolation test methods for preliminary percolation/infiltration information. Percolation testing results are presented in **Table 4**.

- Excavate four (4) exploratory trenches (T-1 through T-4) utilizing a backhoe in readily accessible but widely separated areas of the subject property at depths from approximately 6.5 to 9 feet below the existing ground surface.

- The locations of each of the offsite exploratory borings (for the proposed offsite sewer) are presented on **Figure 2** (Aerial Site Map/Offsite Boring Location Plan). The locations of the exploratory borings, exploratory trenches and percolation test pits on the subject property are presented on **Figure 3** (Field Exploration Plan).

- An evaluation of seismicity and geologic hazards to include an evaluation of faulting.

- Completion of laboratory testing of representative earth materials encountered onsite to ascertain their pertinent soils engineering properties, including corrosion potential (**Appendix B**).

- The preparation of this report which presents our preliminary findings, conclusions, and recommendations.

2.0 BACKGROUND

2.1 Subject Property Description

Based on the information provided by Anderson Consulting Engineers, Inc. ("Client"), and a review of the Google Earth© online database, the subject property consists of approximately 80-acres of undeveloped vacant land located at the northwest corner of the intersection of Oliver Street and Ironwood Avenue, in the City of Moreno Valley, Riverside County, California. Nason Street forms the majority of the western boundary; Ironwood borders the south; and Oliver Street forms the eastern boundary. Vacant land is present to the north. In general, the area is characterized by rural residential and vacant land. Proposed development is for multi or single-family residential.

We understand that an offsite sewer alignment is proposed which is located approximately ¼ miles south of the main subject property area. The sewer alignment is proposed to be extended approximately 900 feet to the south from the existing terminus on Oliver Street near the intersection with Carol Place.

The subject property is approximately situated at 33.9448° north latitude and 117.1871° west longitude (GoogleEarth®, 2013).

2.2 Site Topography

A review of the Sunnymead, California 7.5-minute topographic quadrangle (USGS, 2012) and Project Exhibit/topographic map prepared by Anderson Consulting Engineers, Inc. indicates that the subject property elevation varies from approximately 1,840 to 1,980 feet above mean sea level (amsl). From east-west across the property is a series of north-south oriented ridges and alternating drainage gullies in the lower, southern portion of the property. The intervening ridges are generally about 5 to 10 feet higher in elevation than the adjacent drainage gullies. Rounded granitic outcrops are exposed in the northwestern and northeastern sections of the subject property. The site topography can be generally described as a relatively well-dissected alluvial fan descending from the eroded hills to the north. The overall surface gradient across the property is gently to moderately south or south-southeast.

2.3 Geologic Setting

The subject property and vicinity lies within the Peninsular Ranges Geomorphic Province of California (CGS, 2002). The Peninsular Ranges Geomorphic Province extends from the Transverse Ranges Geomorphic Province and the Los Angeles Basin, south to Baja California. This province varies in width from about 30- to 100-miles. It is bounded on the west by the Pacific Ocean, on the south by the Gulf of California and on the east by the Colorado Desert Province. The Transverse Ranges Geomorphic Province bounds the Peninsular Ranges on the north. The Peninsular Ranges are essentially a series of northwest-southeast oriented fault blocks. Major fault zones and subordinate fault zones found in the Peninsular Ranges Province typically trend in a northwest-southeast direction.

Regional geologic maps of the subject property vicinity (Morton et al., 2004) indicate the property is underlain by Cretaceous-age plutonic rocks composed of tonalite and Holocene age Younger Alluvial Fan deposits. Outcroppings of the weathered tonalite bedrock are exposed in the northwestern and northeastern portions of the property. Over the remainder of the property, the tonalite bedrock was found to be weathering into a soil with a "decomposed granite" or "dg" texture at depth in the exploratory borings and trenches and in general is covered with several feet of alluvial and colluvial (younger alluvial fan) soils also derived from the weathered tonalite. The alluvial and colluvial soils are generally comprised of relatively loose to dense silty sand. The property is relatively undeveloped and artificial fill was not encountered during our field exploration at the property.

Due to the proximity of the subject property area to several nearby active faults, strong ground shaking could occur at the property as a result of an earthquake on any one of the faults. Our review indicates that there are no known active faults crossing the property and the property is not within a State of California Earthquake Fault Zone (Jennings, 1994; Hart and Bryant, 1997, CDMG, 1974; 1998). Due to the presence of shallow bedrock and the lack of shallow groundwater at the property, the property is considered as having a low susceptibility to liquefaction.

2.4 Regional Groundwater

A seismic hazard zone map and report have not been completed for the Sunnymead Quadrangle, therefore, the depth to the historic high groundwater at the subject property is not known. Due to the presence of relatively shallow granitic bedrock at the property, static groundwater is not expected and groundwater was not encountered in any of the exploratory borings or trenches excavated at the property to a maximum explored depth of 50.5 feet below the existing ground surface. Within the lower drainage gullies, up to 30 feet in thickness of silty sand alluvium was encountered. Although not encountered within the alluvium during our field excavation, during times of heavy precipitation or runoff, a localized perched groundwater condition could exist. A review of topographic maps of the general vicinity of the subject property indicates regional topographic relief slopes gently towards the south or south-southeast.

This information suggests that regional groundwater in the property vicinity could be inferred to flow in the same general topographic direction.

3.0 FAULTING AND SEISMICITY

The portion of Southern California that includes the subject property is considered to be seismically active. Due to the proximity of the property area to several nearby active faults, strong ground shaking could occur at the property as a result of an earthquake on any one of the faults. Our review indicates that there are no known active faults crossing the property (Blake, 2000) and the property is not within an Earthquake Fault Zone (Hart and Bryant, 1997). It is our opinion, therefore, that the likelihood of surface fault rupture at the property is low. **Table 1** lists the major active faults within 25 miles that are likely to affect the property.

TABLE 1
Summary of Major Active Faults

	Fault Name	Approximate Distance From Site miles (kilometers)	Maximum Moment Magnitude
1	San Jacinto-San Jacinto Valley	1.5 (2.4)	6.9
2	San Jacinto-San Bernardino	5.8 (9.3)	6.7
3	San Andreas – San Bernardino M-1	12.1 (19.5)	7.5
4	San Andreas – SB-Coach. M-2b	12.1 (19.5)	7.7
5	San Andreas – SB-Coach. M-1b-2	12.1 (19.5)	7.7
6	San Andreas – Whole M-1a	12.1 (19.5)	8.0
7	North Frontal Fault Zone (West)	19.4 (31.2)	7.2
8	San Jacinto – Anza	21.0 (33.8)	7.2
9	Elsinore (Glen Ivy)	21.7 (35.0)	6.8
10	Cucamonga	21.9 (35.2)	6.9
11	Elsinore (Temecula)	22.8 (36.7)	6.8
12	Cleghorn	23.1 (37.2)	6.5
13	Chino-Central Ave. (Elsinore)	23.3 (37.5)	6.7

3.1 Seismic Parameters and Peak Ground Acceleration

Maximum considered ground motion maps provided in the California Building Code (CBC, 2013) were utilized with coordinates of 33.9448° north latitude and 117.1871° west longitude, to determine the subject property seismic parameters. EEI utilized seismic design criteria provided in the CBC (2013).

In accordance with the guidelines of the CBC (2013), the spectral parameters for the subject property (based on a Site Class B soil) are estimated to be S_s = 2.166g and S_1 = 0.982g. Review of the geotechnical data obtained during our subsurface exploration, however, indicates that the property should be classified as Class D per the CBC (Table 1613.5.2). Consequently, Site Coefficients F_a= 1.000 and F_v = 1.500 appear to be appropriate for the property. Based on this information, the adjusted maximum considered earthquake spectral response parameters S_{MS} = 2.166g and S_{M1} = 1.472g are recommended for seismic design of the project. Assuming an occupancy category of II (Table 1604A.5), an S_{DS} value of 1.444g and an S_{D1} value of 0.982g, the proposed building at the property can be assigned a seismic design category of D [Table 1613.5.6 (1) and (2)]. Final selection of the appropriate seismic design coefficients should be made by the structural consultant based on the local laws and ordinances, expected building response, and desired level of conservatism.

Seismic Hazard Response Parameters are listed in **Table 2**.

TABLE 2
Seismic Hazard Response Parameters and Design Parameters CBC (2013)

Latitude: 33.9448° - Longitude: -117.1871° Seismic Parameter	Period (Sec)		Value
Mapped Spectral Acceleration Value, Soil Class B	0.2	S_s	2.166g
Mapped Spectral Acceleration Value, Soil Class B	1.0	S_1	0.982g
Site Coefficient, Subject Site Soil Classification D per 2013 CBC Table 1613.5.2	--	F_a	1.000
Site Coefficient, Subject Site Soil Classification D per 2013 CBC Table 1613.5.2	--	F_v	1.500

Building Assigned Seismic Design Category per Table 1613.5.6 (1) and (2)	--	--	D

3.2 Ground Lurching or Shallow Ground Rupture

Based on the geography, topography and site-specific geotechnical conditions encountered during our preliminary geotechnical evaluation at the subject property, we consider the potential for ground lurching or shallow ground rupture at the property to be low; however, due to the active seismicity of California, this possibility cannot be completely ruled out. In light of this, the unlikely hazard of lurching or ground-rupture should not preclude consideration of "flexible" design for onsite utility lines and connections.

3.3 Liquefaction

Liquefaction is a phenomenon in which the strength and stiffness of a soil is reduced by earthquake shaking or other rapid loading. Liquefaction and related phenomena have been responsible for substantial structural damage in historical earthquakes, and are a design concern under certain conditions. Liquefaction occurs in saturated soils that are soils in which the space between individual particles is completely filled with water. This pore water exerts a pressure on the soil particles that influences how tightly the particles themselves are pressed together.

Prior to an earthquake, pore water pressure is typically low; however, earthquake motion can cause the pore water pressure to increase to the point where the soil particles can readily move with respect to each other. When liquefaction occurs; the strength of the soil decreases and the ability of a soil deposit to support structural loads are reduced.

A seismic hazard zone map and report for the Sunnymead Quadrangle has not been issued by the California Geological Survey (CGS) so the subject property is, therefore, not situated within a mapped Liquefaction Zone. The majority of the property is underlain by generally loose to medium dense alluvial and colluvial deposits that overlie relatively shallow granitic bedrock. The alluvial and colluvial soils are subject to removal and recompaction during site grading for the proposed residential development. It appears that liquefaction is not a significant geotechnical concern at the property.

Cyclic mobility is a liquefaction phenomenon, triggered by cyclic loading, occurring in soil deposits with static shear stresses lower than the soil strength. Deformations due to cyclic mobility develop incrementally because of static and dynamic stresses that exist during an earthquake. Lateral spreading, a common result of cyclic mobility, can occur on gently sloping and on flat ground close to rivers and lakes. These conditions do exist within the subject property, however, based on the conceptual site plan, the property should be relatively level following rough grading with a lack of free channel faces and cyclic mobility should not be an issue post-grading.

3.4 Seismic Induced Settlement

Seismically induced settlement can occur due to reorientation of soil particles during strong shaking of unsaturated sands, as well as in response to liquefaction of saturated loose granular soils.

Based on our evaluation and the geotechnical data obtained from our exploratory borings and trenches, we estimate the total seismic-induced settlement to be less than 1-inch. Differential earthquake induced settlements are estimated to be less than 0.5-inches over a 50-foot span.

4.0 FIELD EXPLORATION AND LABORATORY TESTING

4.1 Field Exploration

Field work for our geotechnical evaluation was conducted on October 16 and 17, 2014. A total of four (4) hollow stem auger borings were drilled on the subject property. Boring depths ranged from 11 feet to 50.5 feet below the existing ground surface. Three (3) additional hollow stem auger borings were drilled offsite in the area of the proposed sewer line extension. All three borings were drilled to an approximate depth of 26.5 feet below existing grade. In addition to the hollow stem auger borings, four (4) exploratory backhoe trenches were excavated on the subject property to depths ranging from 6.5 to 9 feet below existing grade. All exploratory borings and trenches were logged under the supervision of a Registered Professional Engineer and/or Certified Engineering Geologist at EEI. Boring and trench locations were adjusted as necessary due to existing utilities and improvements.

Blow count (N) values were determined utilizing a 140 pound automatic hammer, falling 30-inches onto a Standard Penetration Test (SPT) split-spoon sampler and a Modified California split-tube sampler. A truck mounted hollow-stem auger (HSA) drill rig and rubber-tired backhoe were used during field work. The blows per foot (N value) required to advance the 18-inch long SPT and 12-inch long Modified California split-tube samplers was measured at various initial depths followed by 5-foot intervals, recorded on the boring logs. The boring logs and trench logs for the field exploration are presented in **Appendix A**-Soil Classification Chart and Boring & Trench Logs. Relatively "undisturbed" samples were collected in a 2.42-inch (inside diameter) California Modified split-tube sampler for visual examination and laboratory testing in the exploratory borings. The soils were classified in accordance with the Unified Soil Classification System (ASTM, 2008). Representative bulk samples were also collected from both the exploratory borings and trenches for appropriate laboratory testing.

4.2 Subsurface Conditions

The results of our geotechnical exploration indicate that the proposed residential development is underlain by weathered Cretaceous-age plutonic rocks composed of tonalite. This material was observed to extend beyond the maximum depth of our exploratory borings and test pits (approximately 50.5 feet below existing grades). Alluvial soils up to 30 feet thick were observed to mantle the weathered tonalite bedrock within the lower lying channel/drainage areas.

On the higher, elevated ridge areas on the subject property, colluvial soils were observed to mantle the weathered tonalite bedrock with a thickness varying between 3 and 14 feet. The weathered tonalite bedrock can generally be described as gray, white or black speckled or orange to dark grayish-orange (depending on degree of weathering) with a "granitic" or phaneritic texture and was generally unweathered to highly weathered. Outcroppings of the weathered tonalite bedrock are exposed in the northwestern and northeastern portions of the site. Over the remainder of the property, the tonalite bedrock was found to be weathering into a medium dense to very dense silty sand soil with a "decomposed granite" or "dg" texture at depth in the exploratory borings and test pits. The alluvial and colluvial (younger alluvial fan) soils are also derived from the weathered tonalite. The alluvial and colluvial soils are generally comprised of orange-brown or red-brown, medium brown or light gray brown, fine to coarse, damp to moist, loose to dense silty sand. The property is relatively undeveloped and artificial fill was not encountered during our field exploration at the property.

Our exploratory excavations were performed utilizing light-duty equipment which can provide general excavation characteristics of the onsite materials. Large granitic (tonalite) bedrock outcrops are present on the northeast and northwest portions of the property, along with some isolated rock outcrops within the areas of the proposed development area and generally on the higher elevations of the property. Boulders were present at the surface in these areas, some localized "core rock or floaters" should be anticipated at variable depths in these areas. Based on observed subsurface conditions in the exploratory trench excavations and borings, the "decomposed granite" or "dg" is moderately to highly weathered and/or fractured and was relatively easy to excavate to the depths indicated with a light-duty backhoe and a drill rig equipped with flight auger equipment. No refusal was encountered in any of the exploratory excavations during our field exploration.

In general, the ease of rock excavation or rippability depends on various factors such as rock type, rock hardness and density, the amount of weathering, and the existence and characteristics of discontinuities such as joint spacing, foliation, or fractures.

Due to the relatively dense character of the granitic bedrock encountered onsite, it is likely that oversized rock materials will be created during grading operations. Native earth materials appear to be suitable for use as structural fill provided they are moisture conditioned (as needed), meet EEI's recommendations for size (Section 4.2.2 Fills), and are properly compacted. Dependent upon the grading plan, some of the oversized materials may be re-used in landscape areas.

For the proposed offsite sewer line location, weathered tonalite overlain by 15 feet of alluvial soils was encountered in boring B-5. In boring B-6, colluvial soils at depth were mantled by approximately 10 feet of artificial fill. For boring B-7, colluvial soils were encountered from the surface to the total explored depth. All three offsite borings were advanced to a total depth of 26.5 feet below the existing ground surface. The weathered tonalite bedrock and alluvial soils are generally unchanged from the materials encountered on the subject property. The offsite colluvial soils can generally be described as orange brown to brown, fine to coarse, moist, medium dense to dense silty sand and sandy silt. The artificial fill soils encountered can be described as light brown, fine to coarse, and damp, medium dense silty sand. Refusal was not encountered within any of our exploratory borings or test pits. Detailed descriptions of the encountered soils are provided on the boring logs and test pit logs included as **Appendix A**.

Due to the presence of relatively shallow granitic bedrock at subject property, static groundwater is not expected and groundwater was not encountered in any of the exploratory borings or trenches excavated at the property to a maximum explored depth of 50.5 feet below the existing ground surface. Our review of ground water monitoring data from nearby wells suggests that the groundwater level may fluctuate seasonally and yearly.

It should be noted that fluctuations in the ground water level could also occur due to variations in ground surface topography, subsurface stratifications, precipitation, irrigation, and other factors which may not have been evident at the time of our exploration.

4.3 Laboratory Testing and Classification

Representative samples were selected for laboratory testing to confirm their field classification(s). Field descriptions and classifications were visually classified according to the American Society for Testing and Materials (ASTM) D2488 which classifies soils under the Unified Soil Classification System (USCS). Representative soil samples were tested in the lab for grain size distribution, liquid limits, and plastic limits to determine actual classifications by ASTM D2487-Standard Practice for Classification of Soils for Engineering Purposes in accordance to the USCS. Final classifications of soils can be found on the boring logs in **Appendix A** and the laboratory test data in **Appendix B**.

4.3.1 Moisture Content and Dry Density

The in-situ moisture content and dry density of soils were determined for soil samples obtained from the borings. Moisture contents and dry densities of soils help to determine engineering design parameters for foundations, retaining walls, and other engineered structures. Moisture content on soil samples was conducted in general accordance with ASTM D2216, and was recorded as a percentage. In-situ moisture content and dry density information for soil samples retrieved from the field can be found on the boring logs located in **Appendix A**.

4.3.2 Grain Size Distribution

To help check field classifications of soils, the grain size distribution of representative soil samples was determined. In order to find the percentages of different sized particles in a particular soil stratum, soils were tested in general accordance with ASTM D422-Standard Test Method for Particle-Size Analysis of Soils. Grain size distribution curves and gradation results are presented in **Appendix B.**

4.3.3 Maximum Dry Density and Optimum Moisture Content

The maximum dry density and optimum moisture content were determined from a bulk sample obtained from boring B-1 at depths between 0 and 5 feet below existing grade. Our testing was performed in general accordance with ASTM D1557, Method A. Results of our testing are presented in **Appendix B.**

4.3.4 Direct Shear

Direct shear testing was conducted on three representative samples of the upper soils. One sample was remolded to 90 percent of their maximum dry density (based on ASTM D1557), and the other two samples in its natural state, to measure its shear strength characteristics for engineering purposes. The samples were inundated for at least 18 hours. The samples were placed in a shear box and a normal load was applied (10, 20, and 40 kilogram weights were used). The samples were then sheared at a controlled strain rate in a direct shear apparatus that measures horizontal displacement and shear resistance. Shear testing was run in general accordance with ASTM D3080. The results of our testing are presented in **Appendix B.**

4.3.5 Expansion Index

A soil sample from boring B-1 within the upper 5 feet of existing grade was tested for its expansion potential. Our expansion index testing was conducted in general accordance with ASTM D4829. The results of our expansion index testing are presented in **Appendix B.**

4.3.6 Sulfate/Corrosion

One representative sample of onsite earth material was collected for analysis at Clarkson Laboratory and Supply, Inc. located in Chula Vista, California for corrosion/soluble sulfate potential. This corrosion testing included soil minimum resistivity and pH by California Test 643, sulfate by California Test 417, and chloride by California Test 422. Results of these tests are presented in **Appendix B**.

It should be understood that the results provided in **Appendix B** are based upon pre-development conditions. Verification testing is recommended at the conclusion of grading on samples collected at or near finish grade.

5.0 CONCLUSIONS

Based on our field exploration, laboratory testing and engineering and geologic analysis, it is our opinion that the subject property is suitable for the proposed new development and associated improvements from a geotechnical engineering and geologic viewpoint; however, there are existing geotechnical conditions associated with the property that will warrant mitigation and/or consideration during planning stages. If site plans and/or the location of the proposed residential buildings or proposed offsite sewer line are revised, additional field studies may be warranted to address proposed site-specific conditions. As a result, EEI is providing the following conclusions:

- A total of four (4) hollow stem auger borings were drilled on the subject property. Boring depths ranged from 11 feet to 50.5 feet below the existing ground surface. Three (3) additional hollow stem auger borings were drilled offsite in the area of the proposed sewer line extension. All three borings were drilled to an approximate depth of 26.5 feet below existing grade. In addition to the hollow stem auger borings, four (4) exploratory backhoe trenches were excavated on the subject property to depths ranging from 6.5 to 9 feet below existing grade. The subject property is underlain by weathered Cretaceous-age plutonic rocks composed of tonalite. This material was observed to extend beyond the maximum depth of our exploratory borings and test pits (approximately 50.5 feet below existing grades). Alluvial soils up to 30 feet thick were observed to mantle the weathered tonalite bedrock within the lower lying channel/drainage areas. On the higher, elevated ridge areas on the subject property, colluvial soils were observed to mantle the weathered tonalite bedrock with a thickness varying between 3 and 14 feet. The weathered tonalite bedrock was can generally be described as gray, white or black speckled or orange to dark grayish-orange (depending on degree of weathering) with a "granitic" or phaneritic texture and was generally unweathered to highly weathered and very soft to moderately hard. The alluvial and colluvial (younger alluvial fan) soils are also derived from the weathered tonalite. The alluvial and colluvial soils are generally comprised of orange-brown or red-brown, medium brown or light gray brown, fine to coarse, damp to moist loose to dense silty sand.

- On the subject property, the weathered tonalite bedrock was observed to be mantled by up to approximately a 30-foot thick layer of alluvium in the lower drainage/wash areas while a relatively thin layer of colluvial soils, also mainly silty sand was observed in the exploratory borings and test pits on the higher "ridges".

- For the proposed offsite sewer line location, weathered tonalite overlain by 15 feet of alluvial soils was encountered in boring B-5. In boring B-6, colluvial soils at depth were mantled by approximately 10 feet of artificial fill. For boring B-7, colluvial soils were encountered from the surface to the total explored depth. All three offsite borings were advanced to a total depth of 26.5 feet below the existing ground surface. The weathered tonalite bedrock and alluvial soils are generally unchanged from the materials encountered on the subject property. The offsite colluvial soils can generally be described as orange brown to brown, fine to coarse, moist, loose to medium dense silty sand and sandy silt. The artificial fill soils encountered can be described as light brown, fine to coarse, and damp, loose to medium dense silty sand. No refusal was encountered in any of the onsite or offsite exploratory boring or test pit locations.

- We understand that the Client is considering purchasing the subject property for a residential project. Based on a Project Exhibit provided to EEI by Anderson Consulting Engineers, Inc., it appears that the subject property will be developed into approximately 146 residential building pads and associated streets and other improvements. A future offsite sewer extension is proposed for the right-of-way near the southern terminus of Oliver Street approximately ¼ south of the subject property. The approximate depth of the proposed sewer is about 25 feet below the existing ground surface within the Eastern Municipal Water District (EMWD) water main right-of-way. No further information is known at this time.

- Groundwater was not encountered in any of our onsite or offsite exploratory borings or exploratory test pits to the depths explored (approximately 50.5 feet below existing grades). It should be noted that variations in groundwater may result from fluctuations in the ground surface topography, subsurface stratification, precipitation, irrigation and other factors that may not have been evident at the time of our subsurface exploration.

- Laboratory test results indicate that the near surface materials are near neutral (pH = 7.1) and are moderately corrosive to ferrous metals with a minimum resistivity value of 5,200 ohm-cm. Laboratory testing of the upper soils yielded a soluble sulfate concentration of 0.005 percent and a chloride concentration of 0.007 percent, indicating a negligible corrosion potential to reinforced concrete.

- The results of our laboratory Expansion Index (EI) testing indicate an expansion index of 0, for the tested soils which represents a very low expansion potential.

- The subject property is located within an area of Southern California recognized as having a number of active and potentially-active faults. Our review indicates that there are no known active faults crossing the property and the property is not located within an Earthquake Fault Zone. The nearest active faults that could affect the property are the San Jacinto Valley segment of the San Jacinto Fault Zone, located approximately 1.5 miles from the property, the San Bernardino segment of the San Jacinto Fault Zone, located approximately 5.8 miles from the area of study, the San Bernardino M-1 segment of the San Andreas Fault Zone, the San Bernardino-Coachella Valley M-2b segment of the San Andreas Fault Zone, the San Bernardino-Coachella Valley M-1b-2 segment of the San Andreas Fault Zone and the San Bernardino-Coachella Valley M-1a segment of the San Andreas Fault Zone, all located approximately 12.1 miles from the area of study. Each of these active faults is capable of generating severe ground shaking at the property. A list of active faults within an approximate 25 mile radius is presented in **Table 1**.

- Based on EEI's evaluation, earth materials underlying the subject property are not considered susceptible to liquefaction or significant amounts of seismic settlement. Based on EEI's evaluation, the earth materials underlying the subject property of the proposed development appear to be susceptible to some seismically induced settlement on the order of less than one-inch with differential settlements of less than 0.5-inches over a 50-foot span. Liquefaction-induced lateral spreading does not appear to be a concern at the subject property due to the lack of shallow groundwater, the lack of nearby open face channels and the relatively shallow depth to bedrock.

- At this time and for the purposes of this Due Diligence Level Preliminary Evaluation, we cannot present specific footing recommendations that can be incorporated in the structural design, given that we do not have a scope of the proposed project, no grading or foundation plans were available at the time and no information was provided to us other than the Client is considering purchasing the property for future development.

6.0 RECOMMENDATIONS

The recommendations presented herein should be considered as preliminary for the purpose of characterizing the geotechnical and geologic conditions at the subject property prior to purchasing the property, and for preliminary information to aid the initial planning and design phases of development. Guidelines for site preparation, earthwork, and onsite improvements are provided in the following sections based on a limited number of widely spaced exploratory borings and test pits, and the assumption that the planned onsite development will consist of single-family, wood-frame, slab-on-grade 1- to 2-story residential structures and the planned offsite construction for the proposed sewer line. For more detailed and specific recommendations for the design and planning of the proposed structures at the property, we recommend to supplement this Due Diligence Level Preliminary Geotechnical Evaluation with an additional Geotechnical Evaluation. This additional Geotechnical Evaluation would include a supplementary subsurface evaluation, incorporating additional hollow stem auger borings (HSA), to identify more specifically and in areas not covered by this Due Diligence Level Preliminary Geotechnical Evaluation, the subject property's subsurface conditions and other zones potentially susceptible to seismically induced settlement to the depths explored.

6.1 General

Grading should conform to the guidelines presented in the 2013 California Building Code (CBC, 2013), as well as the requirements of the City of Moreno Valley and the County of Riverside. Additionally, general Earthwork and Grading Guidelines are provided herein as **Appendix C**.

During earthwork construction, removals and reprocessing of fill materials, as well as general grading procedures of the contractor should be observed and the fill placed selectively tested by representatives of the geotechnical engineer, EEI. If any unusual or unexpected conditions are exposed in the field, they should be reviewed by the Geotechnical Engineer and if warranted, modified and/or additional remedial recommendations will be offered. Specific guidelines and comments pertinent to the planned development are provided herein.

The recommendations presented herein have been completed using the preliminary information provided to us regarding site development. If information concerning the proposed development is revised, or any changes in the design and location of the proposed property improvements are made, the preliminary conclusions and recommendations contained in this report should not be considered applicable unless the changes are reviewed and conclusions of this report modified or approved in writing by this office.

6.2 Site Preparation and Grading

Debris and other deleterious material, such as organic soils and/or environmentally impacted earth materials should be removed from the subject property prior to the start of grading. Areas to receive fill should be properly benched in accordance with current industry standards of practice and guidelines specified in the CBC and the requirements of the local jurisdiction.

Existing utilities should be removed within the proposed building envelope. Abandoned trenches should be properly backfilled and tested. If unanticipated subsurface improvements (utility lines, septic systems, wells, utilities, etc.) are encountered during earthwork construction, the geotechnical engineer should be informed and appropriate remedial recommendations would then be provided.

6.3 Remedial Earthwork

The encountered portions of the existing surficial soils including the upper portions of the alluvial and colluvial soils were observed to be somewhat loose and variable in moisture content and relative density. As such, they are considered potentially compressible and unsuitable for the support of settlement-sensitive structures or engineered fill in their current condition. Therefore, where not already removed by the proposed site grading, the existing materials should be completely removed and recompacted in the areas to receive the proposed building improvement and other settlement-sensitive improvements. Based on the results of our subsurface exploration, we recommend that these removals extend to approximate depths on the order of a minimum of 4 feet to a maximum of 30 feet below the existing ground surface, or 24-inches below the bottoms of the proposed foundations. At the approximate location of boring B-1, 30 feet of relatively loose to medium dense silty sand alluvium was encountered above the tonalite bedrock and should be removed to a depth of 30 feet. A similar situation likely exists in other, lower elevation portions of the site within the drainage channels.

Following removal of the upper soils, the bottom of the resulting excavation(s) should be observed by a representative of EEI to check that unsuitable materials have been sufficiently removed. It should be understood that based on the observations of our field representative, localized deeper removals may be recommended. The base of the removal area should be level to avoid differential fill thicknesses under proposed improvements. This remedial earthwork should extend at least 5 feet outside the proposed building limits and/or 5 feet beyond the area to receive fill. Note that vertical sides exceeding 5 feet in depth may be prone to sloughing and may require laying back to an inclination of 1:1 (horizontal to vertical).

After removal of the upper soils and observation of the excavation bottoms, the over-excavated areas should be scarified to a minimum depth of 6-inches, moisture conditioned as needed to achieve at least optimum moisture content and re-compacted to at least 90 percent of the maximum dry density (based on ASTM D1557). The over-excavated areas should then be backfilled with onsite and/or imported soils that are placed and compacted as recommended herein until design finish grades are reached.

6.4 Yielding Subgrade Conditions

The soils encountered at the subject property can often exhibit "pumping" or yielding once they become saturated. This can often occur in response to periods of significant precipitation, such as during the winter rainy season, or if the bottom of an excavation is situated relatively close to the groundwater level. In order to help stabilize the yielding subgrade soils within the bottom of the removal areas, the contractor can consider the placement of uniform sized, ¾- to 2-inch crushed rock within areas exhibiting the "pumping" conditions. The crushed rock should be properly tracked into the underlying soils such that it is adequately intruded into and interlocks with the soils. We expect that a 6- to 12-inch thick section of the crushed rock will be required.

Following the placement and tracking of the gravel layer into the underlying "pumping" soils, it is recommended that Mirafi 600X stabilization fabric (or approved equivalent) then be placed upon the gravel layer. Fill soils, which should be placed and compacted in accordance with the recommendations presented herein, should then be placed upon the fabric until design finish grades are reached. The gravel and stabilization fabric should extend at least 5 feet laterally beyond the limits of the "pumping" areas. These operations should be performed under the observation and testing of a representative of EEI in order to evaluate the effectiveness of these measures and to provide additional recommendations for mitigative measures, as warranted.

6.5 Fill Placement

The soils encountered at the subject property can often exhibit "pumping" or yielding once they become saturated. This can often occur in response to periods of significant precipitation, such as during the winter rainy season, or if the bottom of an excavation is situated relatively close to the groundwater level. In order to help stabilize the yielding subgrade soils within the bottom of the removal areas, the contractor can consider the placement of uniform sized, ¾- to 2-inch crushed rock within areas exhibiting the "pumping" conditions. The crushed rock should be properly tracked into the underlying soils such that it is adequately intruded into and interlocks with the soils. We expect that a 6- to 12-inch thick section of the crushed rock will be required. Following the placement and tracking of the gravel layer into the underlying "pumping" soils, it is recommended that Mirafi 600X stabilization fabric (or approved equivalent) then be placed upon the gravel layer. Fill soils, which should be placed and compacted in accordance with the recommendations presented herein, should then be placed upon the fabric until design finish grades are reached. The gravel and stabilization fabric should extend at least 5 feet laterally beyond the limits of the "pumping" areas. These operations should be performed under the observation and testing of a representative of EEI in order to evaluate the effectiveness of these measures and to provide additional recommendations for mitigative measures, as warranted.

If import soils are needed, the earthwork contractor should ensure that all proposed fill materials are approved by the Geotechnical Engineer prior to use. Representative soil samples should be made available for testing at least ten working days prior to hauling to the subject property to allow for laboratory tests.

Fill materials should be placed in 6- to 8-inch loose lifts, moisture conditioned as necessary to at least optimum moisture and compacted to a minimum of 90 percent maximum density according to ASTM D1557. The upper 12-inches of pavement subgrade should be moisture conditioned to at least optimum moisture and compacted to at least 95 percent of the maximum dry density as determined by ASTM D1557. Suitable heavy grading equipment should be utilized to properly mix, spread, moisture condition or dry, and compact each fill lift.

Those areas to receive fill (including over-excavated areas) or surface improvements should be scarified at least 6-inches, moisture conditioned to at least one percent over optimum moisture content and recompacted to at least 90 percent of the maximum dry density (based on ASTM D1557).

6.6 Shrinkage and Bulking

Several factors will impact earthwork balancing on the subject property, including shrinkage, bulking, subsidence, trench spoils from utilities and footing excavations, and final pavement section thickness as well as the accuracy of topography.

Shrinkage, bulking and subsidence are primarily dependent upon the degree of compactive effort achieved during construction. For planning purposes, the shrinkage factor is estimated to be on the order of 10 to 15 percent for the onsite natural soils to be utilized as fill. This shrinkage factor may vary with methods employed by the contractor. Subsidence is estimated to be on the order of 0.1 feet. For preliminary planning purposes, bulking of the granitic bedrock derived materials is estimated to be 0 to 10 percent. Losses from site clearing and removal of existing site improvements as well as generation of oversize material may affect earthwork quantity calculation and should be considered.

The previous estimates are intended as an aid for the project engineers in estimating earthwork quantities. It is recommended that the site development be planned to include an area that could be raised or lowered to accommodate final site balancing.

7.0 PRELIMNARY FOUNDATION RECOMMENDATIONS

7.1 General

The conclusions and recommendations presented herein, are based on the assumption that the planned development will consist of two- to four-story wood frame residential structures with slab-on-grade. It is our understanding that these conceptual plans are also part of the due diligence phase of the project and may or may not be the final design. As such, the conclusions and recommendations contained in this Due Diligence Preliminary Geotechnical Evaluation report should be considered preliminary, and should be reviewed, revised and/or approved in writing by EEI at the time the project design is finalized.

Be advised that as part of the foundation design election process, there is always a cost/benefit evaluation. Although we are providing alternatives for foundation design we have not accomplished the cost/benefit evaluation.

7.2 Preliminary Foundation Design

Lightly loaded wood-frame, two- to four-story residential buildings with a slab-on-grade, can be supported on conventional continuous or isolated spread footings bearing upon at least 24-inches of properly compacted fill materials. In preparation for foundation construction, the earthwork contractor should ensure that the site has been prepared as recommended, and that field density tests have been performed to adequately document the relative compaction of the structural fill.

Conventional foundations can be designed to impose dead plus long term live load bearing pressures of 2,000 pounds per square foot (psf). The allowable foundation bearing pressure is for footings having a minimum width of 15-inches and a minimum depth of 18-inches embedment below the lowest adjacent finish grade for one or two story buildings and 18-inches wide and a minimum 24-inches embedment below lowest adjacent finish grade for three or four-story buildings. The allowable soil bearing pressure can be increased by one-third when considering transient loads of short duration, such as wind or earthquake loads. Based on the prevailing geotechnical conditions encountered during our subsurface exploration, we recommend that foundations be reinforced with at least two No. 4 bars placed at the top of the footing and two placed at the bottom.

Horizontal loads acting on foundations and stem walls cast in open excavations against undisturbed native soil or against properly placed and compacted fill will be resisted by friction acting along the base of the footing and by passive earth pressures against the side of the footing and stem wall. The frictional resistance acting along the base of footings founded on suitable foundation soils may be computed using a coefficient of friction equal to 0.30 with the normal dead load.

Passive earth pressures acting against the side of footings and stem walls may be assumed to be equivalent to a fluid weighing 250 pounds per cubic foot. Passive pressure in the upper 1.0-foot should be neglected unless confined by concrete slabs-on-grade or asphalt concrete pavement. The values given above may be increased by one-third for transient wind or seismic loads.

7.3 Footing Setbacks

All footings should maintain a minimum 7-foot horizontal setback from the base of the footing to any descending slope (if existing onsite). This distance is measured from the outside footing face at the bearing elevation. Footings should maintain a minimum horizontal setback of H/3 (H=slope height) from the base of the footing to the descending slope face and no less than seven feet, or greater than 40 feet.

Footings adjacent to unlined drainage swales or underground utilities (if any) should be deepened to a minimum of 6-inches below the invert of the adjacent unlined swale or utilities. This distance is measured from the footing face at the bearing elevation. Footings for structures adjacent to retaining walls should be deepened so as to extend below a 1:1 projection from the heel of the wall. Alternatively, walls may be designed to accommodate structural loads from buildings or appurtenances.

7.4 Construction

The foundation construction considerations contained herein are presented as minimum preliminary recommendations from a soils engineering standpoint. Laboratory test results indicate the onsite soils' swell (expansion) potential is very low. During grading of the site, we recommend that no soil possessing an Expansion Index of more than 20 be placed within 18-inches of finish grade, if possible. As such, design parameters provided herein assume that finish grade soil materials will have a low expansion potential.

Recommendations by the project's design-structural engineer or architect, which may exceed the soils engineer's recommendations, should take precedence over the following minimum preliminary considerations. Final foundation design should be provided based on the expansion potential of the near surface soils encountered during grading.

7.5 Concrete Slab-on-Grade

Interior slabs can be grade supported by structural fill whose placement/compaction is documented by the project soils engineer/engineer geologist as recommended herein. The thickness of the slab should be in accordance with the structural engineer's design. However, based on geotechnical considerations, we recommend that concrete slabs be a minimum of 4-inches in thickness. Concrete slabs should be underlain by at least 2-inches of clean sand with a Sand Equivalent (SE) of at least 30. Where moisture condensation is undesirable, concrete slabs should be underlain with a moisture/vapor retarder consisting of a minimum 10-mil, visqueen membrane, with all laps sealed. The membrane should be underlain by a 2-inch layer of clean sand with the aforementioned sand layer placed over the visqueen to aid concrete curing. To reduce the potential for buildup of hydrostatic pressures, the free draining material under the slabs should have positive drainage with no low lying areas (i.e., depressions) created.

Floor slabs should be suitably reinforced and jointed (in accordance with Structural Engineer's recommendations) so that a small amount of independent movement can occur without causing damage. Based on the encountered geotechnical conditions, we recommend that floor slabs be reinforced with No. 4 bars spaced on 18-inch centers (each way)

The contractor should take the appropriate precautions to make sure that the reinforcement is placed and maintained within the middle one-third of the slab. Exterior slabs, such as walkways and driveways, can be adequately supported on documented structural fill that is at minimum 12-inches in thickness, and placed and compacted in accordance with the recommendations contained herein.

In preparation for slab or flatwork construction, the earthwork contractor should ensure that the onsite soils have been prepared as recommended and that field density tests have been performed to adequately document the relative compaction of the structural fill. Preparation of the native soils should be documented prior to placement of aggregate, structural components and/or fill.

Some minor cracking of slabs can be expected due to shrinkage. The potential for this slab cracking can be reduced by careful control of water/cement ratios in the concrete. The contractor should take appropriate curing precautions during the pouring of concrete in hot or windy weather to reduce the potential for cracking of slabs. We recommend that a slipsheet (or equivalent) be utilized if grouted fill, tile, or other crack-sensitive floor covering is planned directly on concrete slabs. All slabs should be designed in accordance with structural considerations.

All dedicated exterior flatwork should conform to standards provided by the governing agency including section composition, supporting material thickness and any requirements for reinforcing steel. Concrete mix proportions and construction techniques, including the addition of water and improper curing, can adversely affect the finished quality of the concrete and result in cracking and spalling of the slab. We recommend that all placement and curing be performed in accordance with procedures outlined by the American Concrete Institute and/or Portland Cement Association. Special consideration should be given to concrete placed and cured during hot or cold weather conditions. Proper control joints should be provided to reduce the potential for damage resulting from shrinkage.

Laboratory test results indicate that the upper soils contain soluble sulfate concentrations of 0.005 percent and chloride concentrations of 0.007 percent. The results of these analyses indicate a negligible corrosion potential to concrete. As such, Type II cement can be used in concrete elements that will be in contact with the upper soils.

8.0 PAVEMENT DESIGN RECOMMENDATIONS

Deleterious material, excessively wet or dry pockets, concentrated zones of oversized rock fragments, and any other unsuitable yielding materials encountered during grading should be removed. Once compacted fill and/or native soils are brought to the proposed pavement subgrade elevations, the subgrade should be proof-rolled in order to check for a uniform firm and unyielding surface. Representatives of the project geotechnical engineer should observe all grading and fill placement.

The upper 12-inches of pavement subgrade soils should be scarified; moisture conditioned to at least optimum moisture content and compacted to at least 95 percent of the laboratory standard (ASTM D1557). If loose or yielding materials are encountered during subgrade preparation, evaluation should be performed by EEI. Aggregate base materials should be properly prepared (i.e., processed and moisture conditioned) and compacted to at least 95 percent of the maximum dry density as determined by ASTM D1557. Aggregate base materials should conform to Caltrans specifications for Class 2 aggregate base.

All pavement section changes should be properly transitioned. Although not anticipated, if adverse conditions are encountered during the preparation of subgrade materials, special construction methods may need to be employed. A representative of the project geotechnical engineer should be present for the preparation of subgrade and aggregate base.

For design purposes we have assumed a Traffic Index (TI) of 4.5 for the proposed parking areas and 6.0 for drive areas at the subject property. These assumed TI's should be verified as necessary by the Civil Engineer or Traffic Engineer. For preliminary design purposes, we have conservatively assumed a preliminary R-Value of 20 for the materials likely to be exposed at subgrade. The modulus of subgrade reaction (K-Value) was estimated at 70 pounds per square inch per inch (psi/in) for an R-Value of 20 (Caltrans, 1974).

TABLE 3
Preliminary Pavement Design Recommendations

Traffic Index (TI)	Pavement Surface	Aggregate Base Material (1)
4.5 – Parking Stalls	3.0-inches Asphalt Concrete	6.0-inches
6.0 – Main Drive Areas	4.0-inches Asphalt Concrete	8.0-inches
Trash Area and Concrete Pavement	5.5-inches Portland Cement Concrete (2)	Optional

(1) R-Value of 78 for Caltrans Class 2 aggregate base
(2) Reinforcement and control joints placed in accordance with the structural engineer's requirements

The recommended pavement sections provided above are intended as a preliminary minimum guideline. If thinner or highly variable pavement sections are constructed, increased maintenance and repair could be expected. If the ADT (average daily traffic) or ADTT (average daily truck traffic) increases beyond that intended, as reflected by the assumed traffic index used for design, increased maintenance and repair could be required for the pavement section. Final pavement design should be verified by testing of soils exposed at subgrade after grading has been completed. Thicker pavement sections could result if R-Value testing indicates lower values.

9.0 DEVELOPMENT RECOMMENDATIONS

9.1 Landscape Maintenance and Planting

Water is known to decrease the physical strength of earth materials, significantly reducing stability by high moisture conditions. Surface drainage away from foundations and graded slopes should be maintained. Only the volume and frequency of irrigation necessary to sustain plant life should be applied.

Consideration should be given to selecting lightweight, deep rooted types of landscape vegetation which require low irrigation that are capable of surviving the local climate. From a soils engineering viewpoint, "leaching" of the onsite soils is not recommended for establishing landscaping. If landscape soils are processed for the addition of amendments, the processed soils should be re-compacted to at least 90 percent relative compaction (based on ASTM D1557).

9.2 Site Drainage

Positive site drainage should be maintained at all times. Drainage should not flow uncontrolled over slopes or the subject parcel. Runoff should be channeled away from slopes and structures and not allowed to pond and/or seep uncontrolled into the ground. Pad drainage should be directed toward an acceptable outlet. Although not required, roof gutters and down spouts may be considered to control roof drainage, discharging a minimum of 10 feet from the proposed structures, or into a subsurface drainage system. Consideration should be given to eliminating open bottom planters directly adjacent to proposed structures for a minimum distance of ten feet. As an alternative, closed-bottom type planters could be utilized, with a properly designed drain outlet placed in the bottom of the planter.

9.3 Stormwater Disposal Systems

EEI understands that current plans call for runoff generated from the facility to be disposed of in engineered subsurface features onsite.

9.3.1 Percolation Testing

During our subsurface exploration at the subject property, EEI conducted percolation testing in three widely separated locations (P1, P2 and P3) near the southern property boundary at the locations for proposed detention basins as shown on the conceptual site plan. Our testing was performed at an approximate depth of approximately 3 feet below the existing ground surface. A minimum 2-inch layer of ½-inch diameter crushed gravel was placed at the bottom of the excavation prior to testing. The approximate locations of our percolation test borings are provided on **Figure 3**.

Percolation testing was conducted by one of EEI's field geologists under the guidance of a Registered Engineering Geologist and Registered Civil Engineer with EEI. In general accordance with the County of Riverside guidelines for percolation testing, the percolation test locations were pre-soaked by pouring at least 5 gallons of water into the excavation. Testing was started after the hole was allowed to pre-soak for at least one hour. During testing, a minimum of 12-inches of water was placed in the excavation and the rate of the water drop was recorded at approximately 10 minute intervals. This procedure was repeated for the test hole until rates varied generally less than 10 percent for the test hole. We note that a soil profile's percolation rate is not the same as its infiltration rate. Therefore, the measured/calculated field percolation rate was converted to an estimated infiltration rate utilizing a reduction factor known as the Porchet method (Ritzema, 1974). Upon conclusion of testing, the perforated pipe was removed and the test excavation was backfilled. Results of percolation testing are presented in the following table, **Table 4**.

TABLE 4
Percolation Test Results

Test		Depth of Test (feet below existing grade)	Stabilized Percolation Rate (in/hr)	Infiltration Rate (in/hr)
P1		3	3.84	0.82
P2		3	3.60	0.50
P3		3	3.60	0.45

9.3.2 Summary of Findings

Based on the results of our percolation testing, it appears that a preliminary tested infiltration rate of 0.45-inches per hour can be used in preliminary design of subsurface stormwater retention/disposal devices at the property.

9.3.3 Structural Setback from Retention Devices

It is recommended that retention/disposal devices be situated at least three times their depth, or a minimum of 15 feet (whichever is greater), from the outside bottom edge of structural foundations. Structural foundations include (but are not limited to) buildings, loading docks, retaining walls, and screen walls.

9.4 Additional Site Improvements

Recommendations for additional grading, exterior concrete flatwork design and construction can be provided upon request. If in the future, additional property improvements are planned for the subject property, recommendations concerning the design and construction of improvements would be provided upon request.

9.5 Trenching

All temporary excavations for grading purposes and installation of underground utilities should be constructed in accordance with OSHA guidelines and local safety codes. Temporary excavations over 5 feet in height should be evaluated by the project engineer, and could require shoring, sloping, or a combination thereof. Temporary excavations within the onsite materials should be stable at 1:1 inclinations for cuts less than 10 feet in height.

Footing trench excavations for structures and walls should be observed and approved by a representative of the project soils engineer prior to placing reinforcement. Footing trench spoil and excess soils generated from utility trench excavations should be compacted to a minimum relative compaction of 90 percent (based on ASTM D1557) if not removed from the subject property. All excavations should conform to OSHA and local safety codes.

9.6 Utility Backfill

Fill around the pipe should be placed in accordance with details shown on the drawings, and should be placed in layers not to exceed 8-inches loose (unless otherwise approved by the geotechnical engineer) and compacted to at least 90 percent of the maximum dry density as determined in accordance with ASTM D1557 (Modified Proctor). The geotechnical engineer should approve all backfill material. Select material should be used when called for on the drawings, or when recommended by the geotechnical engineer. Care should be taken during backfill and compaction operations to maintain alignment and prevent damage to the joints. The backfill should be kept free from oversized material, chunks of highly plastic clay, or other objectionable material. Backfill soils should be non-expansive, non-corrosive, and compatible with native earth materials. Backfill materials and testing should be in accordance with the CBC (2013), and the requirements of the local governing jurisdiction.

Pipe backfill areas should be graded and maintained in such a condition that erosion or saturation will not damage the pipe bed or backfill. Flooding trench backfill is not recommended. Heavy equipment should not be operated over any pipe until it has been properly backfilled with a minimum of 2 to 3 feet of cover. The utility trench should be systematically backfilled to allow maximum time for natural settlement. Backfill should not occur over porous, wet, or spongy subgrade surfaces. Should these conditions exist, the areas should be removed, replaced and recompacted.

10.0 PLAN REVIEW

Once detailed site and grading plans are available, they should be submitted to this office for review and comment, to reduce the potential for discrepancies between plans and the preliminary recommendations presented herein. If conditions are found to differ substantially from those stated, appropriate recommendations would be provided. Additional field studies may be warranted.

11.0 LIMITATIONS

This Due Diligence Level Preliminary Geotechnical Evaluation has been conducted in accordance with generally accepted geotechnical engineering principles and practices. Findings provided herein have been derived in accordance with current standards of practice, and no warranty is expressed or implied. Standards of practice are subject to change with time. This Preliminary Evaluation report has been prepared for the sole use of Anderson Consulting Engineers, Inc. (Client), within a reasonable time from its authorization. Site conditions, land use (both onsite and offsite), or other factors may change as a result of man-made influences, and additional work may be required with the passage of time.

This Due Diligence Level Preliminary Geotechnical Evaluation should not be relied upon by other parties without the express written consent of EEI and the Client; therefore, any use or reliance upon this geotechnical evaluation by a party other than the Client should be solely at the risk of such third party and without legal recourse against EEI, its employees, officers, or directors, regardless of whether the action in which recovery of damages is brought or based upon contract, tort, statue, or otherwise. The Client has the responsibility to see that all parties to the project, including the designer, contractor, subcontractor, and building official, etc. are aware of this report in its complete form. This report contains information that may be used in the preparation of contract specifications; however, the report is not designed as a specification document, and may not contain sufficient information for use without additional assessment. EEI assumes no responsibility or liability for work or testing performed by others. In addition, this report may be subject to review by the controlling authorities.

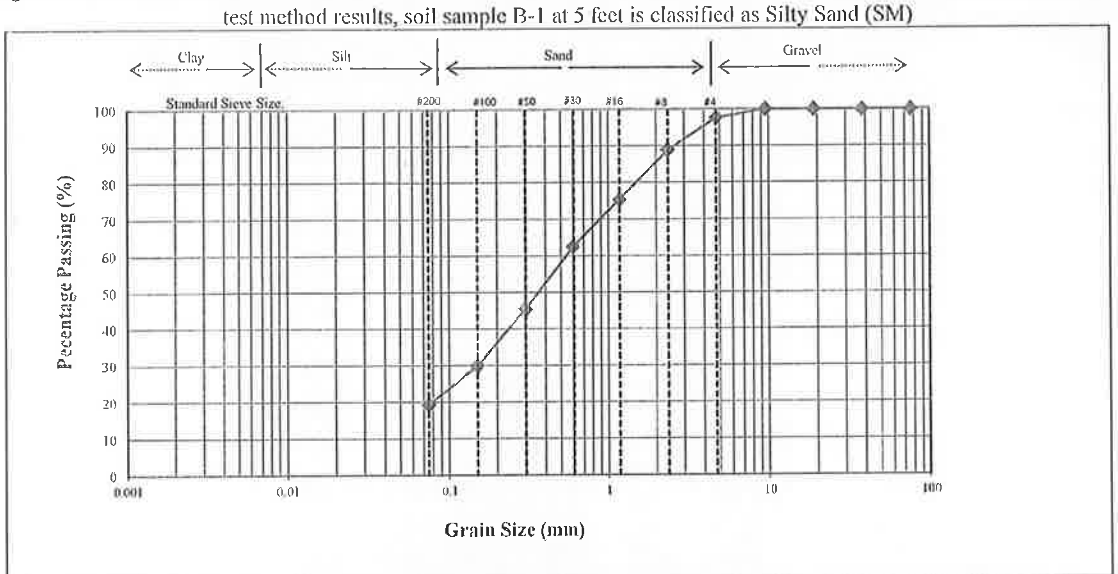
APPENDIX B
LABORATORY TEST DATA

PARTICLE-SIZE ANALYSIS OF SOILS
ASTM METHOD D 422 (SIEVE ANALYSIS)

Sample :	B-1 @ 5 ft.
Total Weight (g)	129.2
Dry Weight (g)	125.8
Wet Sieve Weight (g)	101.5
Initial Moisture (%)	2.7

D10 (mm)	N/A
D30 (mm)	0.15
D60 (mm)	0.53
Cu	N/A
Cc	N/A

According to ASTM D 2487 Unified Soil Classification System (USCS) and ASTM D 422 (Standard Test Method for Particle-Size Analysis) test method results, soil sample B-1 at 5 feet is classified as Silty Sand (SM)



Sieve Size (in)	Sieve Size (mm)	Cumulative Weight of dry soil (gm)	Percent Retained (%)	Percent Passing (%)
3"	76.2		0.0	100.0
1.5"	38.1		0.0	100.0
3/4"	19.05		0.0	100.0
3/8"	9.53		0.0	100.0
#4	4.75	3.0	2.4	97.6
#8	2.36	14.0	11.1	88.9

APPENDIX C
EARTHWORK AND GRADING GUIDELINES

Geotechnical & Environmental Solutions

EARTHWORK AND GRADING GUIDELINES

GENERAL

These guidelines present general procedures and recommendations for earthwork and grading as required on the approved grading plans, including preparation of areas to be filled, placement of fill and installation of subdrains and excavations. The recommendations contained in the geotechnical report are applicable to each specific project, are part of the earthwork and grading guidelines and would supersede the provisions contained hereafter in the case of conflict. Observations and/or testing performed by the consultant during the course of grading may result in revised recommendations which could supersede these guidelines or the recommendations contained in the geotechnical report. Figures A through O are provided at the back of this appendix, exhibiting generalized cross sections relating to these guidelines.

The contractor is responsible for the satisfactory completion of all earthworks in accordance with provisions of the project plans and specifications. The project soil engineer and engineering geologist (geotechnical consultant) or their representatives should provide observation and testing services, and geotechnical consultation throughout the duration of the project.

EARTHWORK OBSERVATIONS AND TESTING

Geotechnical Consultant

Prior to the commencement of grading, a qualified geotechnical consultant (a soil engineer and engineering geologist) should be employed for the purpose of observing earthwork procedures and testing the fills for conformance with the recommendations of the geotechnical report, the approved grading plans, and applicable grading codes and ordinances.

The geotechnical consultant should provide testing and observation so that determination may be made that the work is being completed as specified. It is the responsibility of the contractor to assist the consultant and keep them aware of work schedules and predicted changes, so that the consultant may schedule their personnel accordingly.

All removals, prepared ground to receive fill, key excavations, and subdrains should be observed and documented by the project engineering geologist and/or soil engineer prior to placing any fill. It is the contractor's responsibility to notify the engineering geologist and soil engineer when such areas are ready for observation.

2195 Faraday Avenue • Suite K • Carlsbad, California 92008-7207 • Ph: 760-431-3747 • Fax: 760-431-3748 • www.eeitiger.com

Laboratory and Field Tests

Maximum dry density tests to determine the degree of compaction should be performed in accordance with American Standard Testing Materials test method ASTM designation D-1557-78. Random field compaction tests should be performed in accordance with test method ASTM designations D-1556-82, D-2937 or D-2922 & D-3017, at intervals of approximately two (2) feet of fill height per 10,000 sq. ft. or every one thousand cubic yards of fill placed. These criteria would vary depending on the soil conditions and the size of the project. The location and frequency of testing would be at the discretion of the geotechnical consultant

Contractor's Responsibility

All clearing, site preparation, and earthwork performed on the project should be conducted by the contractor, with observation by geotechnical consultants and staged approval by the appropriate governing agencies. It is the contractor's responsibility to prepare the ground surface to receive the fill to the satisfaction of the soil engineer, and to place, spread, moisture condition, mix and compact the fill in accordance with the recommendations of the soil engineer. The contractor should also remove all major deleterious material considered unsatisfactory by the soil engineer.

It is the sole responsibility of the contractor to provide adequate equipment and methods to accomplish the earthwork in accordance with applicable grading guidelines, codes or agency ordinances, and approved grading plans. Sufficient watering apparatus and compaction equipment should be provided by the contractor with due consideration for the fill material, rate of placement, and climatic conditions. If, in the opinion of the geotechnical consultant, unsatisfactory conditions such as questionable weather, excessive oversized rock, deleterious material or insufficient support equipment are resulting in a quality of work that is not acceptable, the consultant will inform the contractor, and the contractor is expected to rectify the conditions, and if necessary, stop work until conditions are satisfactory.

The contractor will properly grade all surfaces to maintain good drainage and prevent ponding of water. The contractor will take action to control surface water and to prevent erosion control measures that have been installed.

SITE PREPARATION

All vegetation including brush, trees, thick grasses, organic debris, and other deleterious material should be removed and disposed of offsite, and must be concluded prior to placing fill. Existing fill, soil, alluvium, colluvium, or rock materials determined by the soil engineer or engineering geologist as unsuitable for structural in-place support should be removed prior to fill placement. Depending upon the soil conditions, these materials may be reused as compacted fills. Any materials incorporated as part of the compacted fills should be approved by the soil engineer.

Any underground structures such as cesspools, cisterns, mining shafts, tunnels, septic tanks, wells, pipelines, or other structures not located prior to grading are to be removed or treated in a manner recommended by the soil engineer. Soft, dry, spongy, highly fractured, or otherwise unsuitable ground extending to such a depth that surface processing cannot adequately improve the condition should be over excavated down to firm ground and approved by the soil engineer before compaction and filling operations continue. Over excavated and processed soils which have been properly mixed and moisture-conditioned should be recompacted to the minimum relative compaction as specified in these guidelines.

Existing ground which is determined to be satisfactory for support of the fills should be scarified to a minimum depth of six (6) inches, or as directed by the soil engineer. After the scarified ground is brought to optimum moisture (or greater) and mixed, the materials should be compacted as specified herein. If the scarified zone is greater than 6 inches in depth, it may be necessary to remove the excess and place the material in lifts restricted to six (6) inches in compacted thickness.

Existing grind which is not satisfactory to support compacted fill should be over excavated as required in the geotechnical report or by the onsite soils engineer and/or engineering geologists. Scarification, discing, or other acceptable form of mixing should continue until the soils are broken down and free of large fragments or clods, until the working surface is reasonably uniform and free from ruts, hollows, hummocks, or other uneven features which would inhibit compaction as described above.

Where fills are to be placed on ground with slopes steeper than 5:1 (horizontal to vertical) gradient, the ground should be benched. The lowest bench, which will act as a key, should be a minimum of 12 feet wide and should be at least two (2) feet deep into competent material, approved by the soil engineer and/or engineering geologist. In fill over cut slope conditions, the recommended minimum width of the lowest bench or key is at least 15 feet with the key excavated on competent material, as designated by the Geotechnical Consultant. As a general rule, unless superseded by the Soil Engineer, the minimum width of fill keys should be approximately equal to one-half (½) the height of the slope.

Standard benching is typically four feet (minimum) vertically, exposing competent material. Benching may be used to remove unsuitable materials, although it is understood that the vertical height of the bench may exceed four feet. Pre stripping may be considered for removal of unsuitable materials in excess of four feet in thickness.

All areas to receive fill, including processed areas, removal areas, and toe of fill benches should be observed and approved by the soil engineer and/or engineering geologist prior to placement of fill. Fills may then be properly placed and compacted until design grades are attained.

COMPACTED FILLS

Earth materials imported or excavated on the property may be utilized as fill provided that each soil type has been accepted by the soil engineer. These materials should be free of roots, tree branches, other organic matter or other deleterious materials. All unsuitable materials should be removed from the fill as directed by the soil engineer. Soils of poor gradation, undesirable expansion potential, or substandard strength characteristics may be designated unsuitable by the consultant and may require mixing with other earth materials to serve as a satisfactory fill material.

Fill materials generated from benching operations should be dispersed throughout the fill area. Benching operations should not result in the benched material being placed only within a single equipment width away from the fill/bedrock contact.

Oversized materials, defined as rock or other irreducible materials with a maximum size exceeding 12 inches in one dimension, should not be buried or placed in fills unless the location of materials and disposal methods are specifically approved by the soil engineer. Oversized material should be taken offsite or placed in accordance with recommendations of the soil engineer in areas designated as suitable for rock disposal. Oversized material should not be placed vertically within 10 feet of finish grade or horizontally within 20 feet of slope faces.

To facilitate trenching, rock should not be placed within the range of foundation excavations or future utilities unless specifically approved by the soil engineer and/or the representative developers.

If import fill material is required for grading, representative samples of the material should be analyzed in the laboratory by the soil engineer to determine its physical properties. If any material other than that previously analyzed is imported to the fill or encountered during grading, analysis of this material should be conducted by the soil engineer as soon as practical.

Fill material should be placed in areas prepared to receive fill in near-horizontal layers that should not exceed six (6) inches compacted in thickness. The soil engineer may approve thicker lifts if testing indicates the grading procedures are such that adequate compaction is being achieved. Each layer should be spread evenly and mixed to attain uniformity of material and moisture suitable for compaction.

Fill materials at moisture content less than optimum should be watered and mixed, and "wet" fill materials should be aerated by scarification, or should be mixed with drier material. Moisture conditioning and mixing of fill materials should continue until the fill materials have uniform moisture content at or above optimum moisture.

After each layer has been evenly spread, moisture-conditioned and mixed, it should be uniformly compacted to a minimum of 90 percent of maximum density as determined by ASTM test designation, D 1557-78, or as otherwise recommended by the soil engineer. Compaction equipment should be adequately sized and should be reliable to efficiently achieve the required degree of compaction.

Where tests indicate that the density of any layer of fill, or portion thereof, is below the required relative compaction or improper moisture content, the particular layer or portion will be reworked until the required density and/or moisture content has been attained. No additional fill will be placed in an area until the last placed lift of fill has been tested and found to meet the density and moisture requirements, and is approved by the soil engineer.

Compaction of slopes should be accomplished by over-building the outside edge a minimum of three (3) feet horizontally, and subsequently trimming back to the finish design slope configuration. Testing will be performed as the fill is horizontally placed to evaluate compaction as the fill core is being developed. Special efforts may be necessary to attain the specified compaction in the fill slope zone. Final slope shaping should be performed by trimming and removing loose materials with appropriate equipment. A final determination of fill slope compaction should be based on observation and/or testing of the finished slope face.

If an alternative to over-building and cutting back the compacted fill slope is selected, then additional efforts should be made to achieve the required compaction in the outer 10 feet of each lift of fill by undertaking the following:

- Equipment consisting of a heavy short-shanked sheepsfoot should be used to roll (horizontal) parallel to the slopes continuously as fill is placed. The sheepsfoot roller should also be used to roll perpendicular to the slopes, and extend out over the slope to provide adequate compaction to the face slope.

- Loose fill should not be spilled out over the face of the slope as each lift is compacted. Any loose fill spilled over a previously completed slope face should be trimmed off or be subject to re-rolling.

- Field compaction tests will be made in the outer two (2) to five (5) feet of the slope at two (2) to three (3) foot vertical intervals, subsequent to compaction operations.

- After completion of the slope, the slope face should be shaped with a small dozer and then re-rolled with a sheepsfoot to achieve compaction to near the slope face. Subsequent to testing to verify compaction, the slopes should be grid-rolled to achieve adequate compaction to the slope face. Final testing should be used to confirm compaction after grid rolling.

- Where testing indicates less than adequate compaction, the contractor will be responsible to process, moisture condition, mix and recompact the slope materials as necessary to achieve compaction. Additional testing should be performed to verify compaction.

- Erosion control and drainage devices should be designed by the project civil engineer in compliance with the ordinances of the controlling governmental agencies, and/or in accordance with the recommendations of the soil engineer or engineering geologist.

EXCAVATIONS

Excavations and cut slopes should be observed and mapped during grading by the engineering geologist. If directed by the engineering geologist, further excavations or over-excavation and refilling of cut areas should be performed. When fills over cut slopes are to be graded, the cut portion of the slope should be observed by the engineering geologist prior to placement of the overlying fill portion of the slope. The engineering geologist should observe all cut slopes and should be notified by the contractor when cut slopes are started.

If, during the course of grading, unanticipated adverse or potentially adverse geologic conditions are encountered, the engineering geologist and soil engineer should investigate, evaluate and make recommendations to mitigate (or limit) these conditions. The need for cut slope buttressing or stabilizing should be based on as-grading evaluations by the engineering geologist, whether anticipated previously or not.

Unless otherwise specified in soil and geological reports, no cut slopes should be excavated higher or steeper than that allowed by the ordinances of controlling governmental agencies. Additionally, short-term stability of temporary cut slopes is the contractor's responsibility.

Erosion control and drainage devices should be designed by the project civil engineer and should be constructed in compliance with the ordinances of the controlling governmental agencies, and/or in accordance with the recommendations of the soil engineer or engineering geologist.

SUBDRAIN INSTALLATION

Subdrains should be installed in accordance with the approved embedment material, alignment and details indicated by the geotechnical consultant. Subdrain locations or construction materials should not be changed or modified without approval of the geotechnical consultant. The soil engineer and/or engineering geologist may recommend and direct changes in subdrain line, grade and drain material in the field, pending exposed conditions. The location of constructed subdrains should be recorded by the project civil engineer.

COMPLETION

Consultation, observation and testing by the geotechnical consultant should be completed during grading operations in order to state an opinion that all cut and filled areas are graded in accordance with the approved project specifications.

After completion of grading and after the soil engineer and engineering geologist have finished their observations, final reports should be submitted subject to review by the controlling governmental agencies. No additional grading should be undertaken without prior notification of the soil engineer and/or engineering geologist.

All finished cut and fill slopes should be protected from erosion, including but not limited to planting in accordance with the plan design specifications and/or as recommended by a landscape architect. Such protection and/or planning should be undertaken as soon as possible after completion of grading.

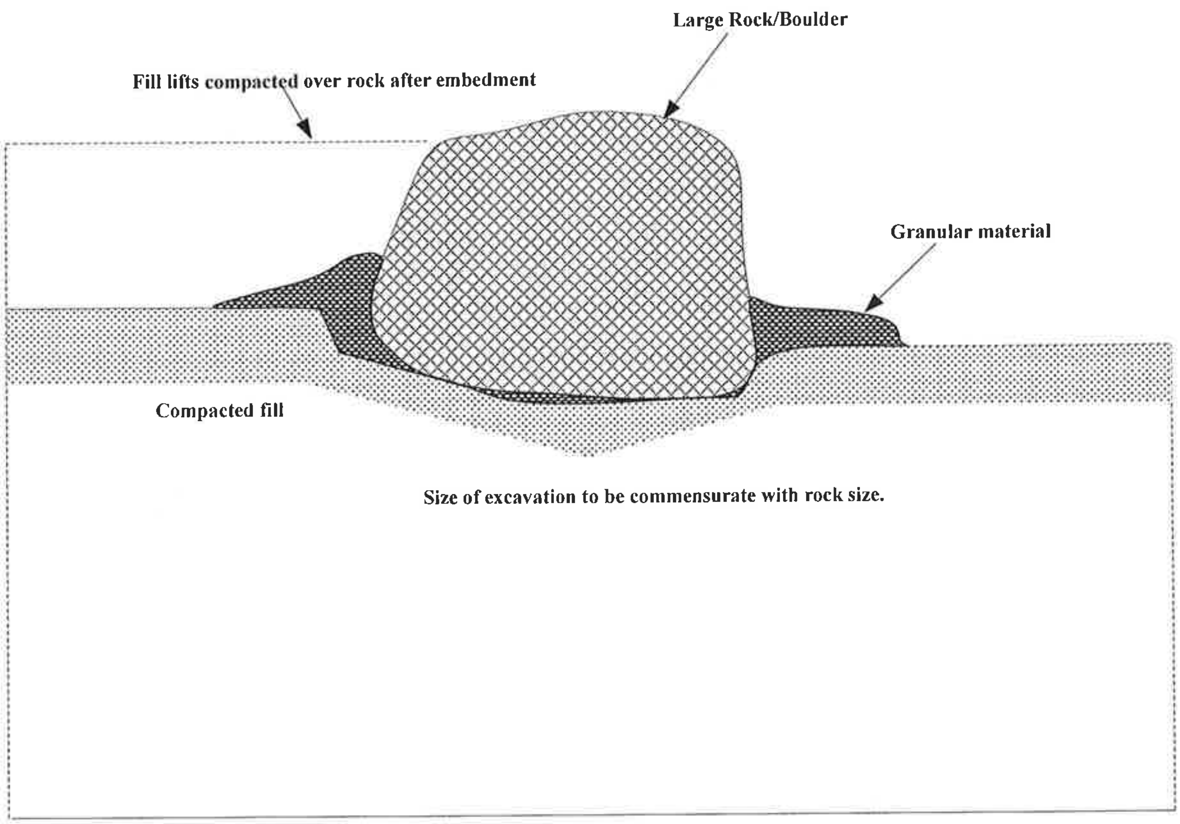
ROCK DISPOSAL PITS



Note:
(1) Large rock is defined as having a diameter larger than 3 feet in maximum size.
(2) Pit shall be excavated into compacted fill to a depth equal to half of the rock size.
(3) Granular soil shall be pushed into the pit and then flooded around the rock using a sheepsfoot to help with compaction.
(4) A minimum of 3 feet of compacted fill should be laid over each pit.
(5) Pits shall have at least 15 feet of separation between one another, horizontally.
(6) Pits shall be placed at least 20 feet from any fill slope.
(7) Pits shall be used only in deep fill areas.

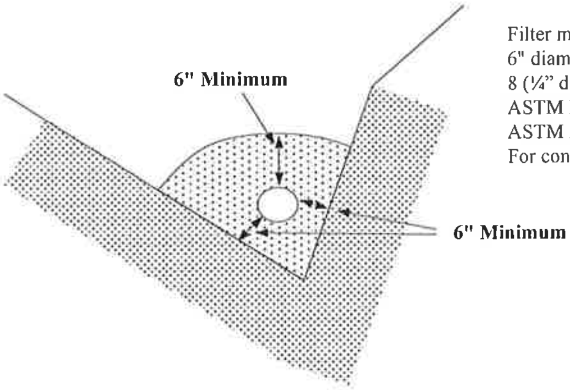
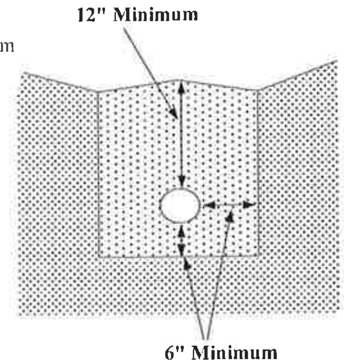
CANYON SUBDRAIN ALTERNATE DETAILS

Alternate 1: Perforated Pipe and Filter Material



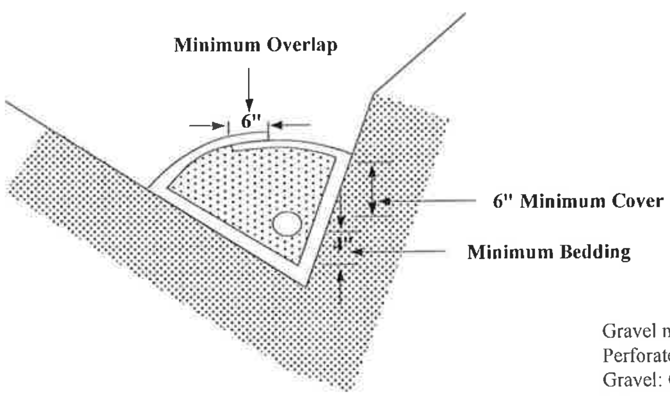
Filter material: Minimum volume of 9 feet^3/linear foot.
6" diameter ABS or PVC pipe or approved substitute with minimum 8 (¼" diameter) perforations per linear foot in bottom half of pipe.
ASTM D 2751, SDR 35 or ASTM D 1527, Schedule 40.
ASTM D 3034, SDR 35 or ASTM D 1785, Schedule 40.
For continuous run in excess of 500 feet use 8" diameter pipe.

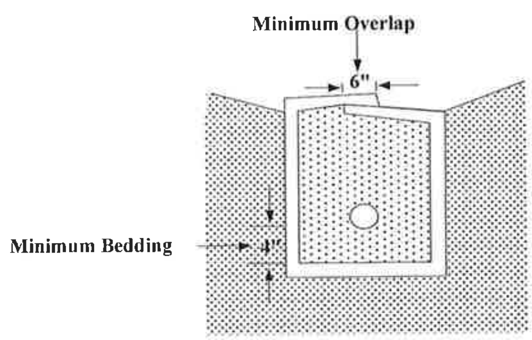


Filter Material

Sieve Size	Percent Passing
1"	100
¾"	90-100
3/8"	40-100
No. 4	25-40
No. 8	18-33
No. 30	5-15
No. 50	0-7
No. 200	0-3

Alternate 2: Perforated Pipe, Gravel and Filter Fabric





Gravel material 9 feet^3/linear foot.
Perforated pipe: see alternate 1.
Gravel: Clean ¾" rock or approved substitute.
Filter Fabric: Mirafi 140 or approved substitute.

Note: Figures not to scale

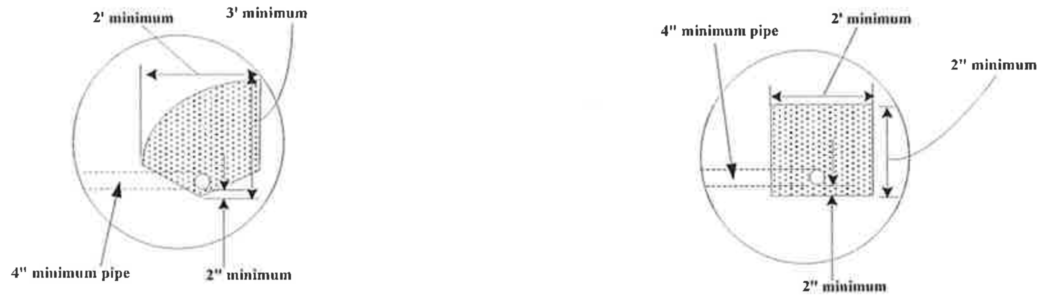
FIGURE N

TYPICAL STABILIZATION BUTTRESS SUBDRAIN DETAIL



Filter Material: Minimum of 5 ft^3/linear foot of pipe or 4 ft^3/linear foot of pipe when placed in square cut trench.

Alternative In Lieu Of Filter Material: Gravel may be encased in approved filter fabric. Filter fabric shall be mirafi 140 or equivalent. Filter fabric shall be lapped a minimum of 12" on all joints.

Minimum 4" Diameter Pipe: ABS-ASTM D-2751, SDR 35 or ASTM D-1527 schedule 40 PVC-ASTM D-3034, SDR 35 or ASTM D-1785 schedule 40 with a crushing strength of 1,000 pounds minimum, and a minimum of 8 uniformly spaced perforations per foot of pipe installed with perforations at bottom of pipe. Provide cap at upstream end of pipe. Slope at 2% to outlet pipe. Outlet pipe shall be connected to the subdrain pipe with tee or elbow.

Note: (1) Trench for outlet pipes shall be backfilled with onsite soil.
(2) Backdrains and lateral drains shall be located at the elevation of every bench drain. First drain shall be located at the elevation just above the lower lot grade. Additional drains may be required at the discretion of the soils engineer and/or engineering geologist.

Filter Material -- Shall be of the following specification or an approved equivalent:

Filter Material

Sieve Size	Percent Passing
1"	100
¾"	90-100
3/8"	40-100
No. 4	25-40
No. 8	18-33
No. 30	5-15
No. 50	0-7
No. 200	0-3

Gravel - Shall be of the following specification or an approved equivalent:

Filter Material

Sieve Size	Percent Passing
1½"	100
No. 4	50
No. 200	8

Sand equivalent: Minimum of 50

1.0 INTRODUCTION

1.1 Purpose

The purpose of this evaluation was two-fold. The first purpose was to provide supplemental geotechnical information to Anderson Consulting Engineers, Inc. ("Client"), regarding the undeveloped subject property at the northwest corner of Ironwood Avenue and Oliver Street (Tract No. 31556) in the City of Moreno Valley, Riverside County, California. The information developed in this Supplemental Geotechnical Evaluation is intended to provide the Client with additional/supplemental subsurface information for portions of the property that were not investigated during EEI's Feasibility-Level Geotechnical Investigation performed in 2014 and also to provide additional/supplemental conclusions and recommendations for the proposed property development.

The second purpose of this Supplemental Geotechnical Evaluation was to provide the Client with geotechnical information regarding the subsurface conditions at the proposed bore and receiving pit locations for the 60 Freeway undercrossing of Tract No. 31556 offsite sewer to determine general subsurface conditions and to provide conclusions/recommendations based on the ease/difficulty of excavations at the pit locations (Site Vicinity Map-**Figure 1**, Aerial Site Map-**Figure 2**).

This Supplemental Geotechnical Evaluation has been conducted in general accordance with the accepted geotechnical engineering principles and in general conformance with the proposed and optional scope of services presented in the approved proposal and cost estimate for the project by EEI, dated March 10, 2015.

EEI conducted an onsite field exploration on April 16 and 17, 2015 that included drilling and sampling of eight (8) hollow stem auger geotechnical borings (borings B-8 through B-15) for the proposed development at the undeveloped subject property. Two (2) additional hollow stem auger geotechnical borings (borings B-16 and B-17) were performed at the proposed bore and receiving pit locations at the 60 freeway undercrossing for Tract No. 31556 offsite sewer, located approximately 3,500 feet south of the undeveloped subject property at the northwest corner of the Ironwood Avenue/Oliver Street intersection. This Supplemental Geotechnical Evaluation has been prepared for the sole use of Anderson Consulting Engineers, Inc. Other parties, without the express written consent of EEI and the Client should not rely upon this Supplementa; Geotechnical Evaluation.

1.2 Project Description

The Client has requested that EEI perform a Supplemental Geotechnical Evaluation of the subject property (Tract No. 31556) consisting of approximately 80-acres of undeveloped vacant land located at the northwest corner of the intersection of Oliver Street and Ironwood Avenue, in the City of Moreno Valley, Riverside County, California. EEI has previously performed a Due Diligence Level Feasibility Geotechnical Evaluation for the property (EEI Project No. GLO-71982.4, Dated November 25, 2014) consisting of the excavation of four (4) small diameter borings (borings B-1 through B-4), 4 (four) backhoe test pits (T-1 through T-4) and three (3) percolation test pits (P-1 through P-3) on the property for the proposed residential development. Nason Street forms the majority of the western boundary; Ironwood borders the south; and Oliver Street forms the eastern boundary. Vacant land is present to the north. In general, the area is characterized by rural residential and vacant land. Proposed development is for 146 multi- or single-family residential lots.

Based on a review of the sewer plans provided by Anderson Consulting Engineers ("Client") and a review of the GoogleEarth© online database, the proposed project consists of the construction of an offsite sewer to service future Tract No. 31556.

The proposed offsite sewer alignment appears to begin at the northwest corner of the intersection of Ironwood Avenue and Oliver Street (which is the southeast corner of Tract No. 31556) and extends south along the existing alignment of Oliver Street which terminates at Carol Place and continues south along the alignment of the proposed future extension of Oliver Street to the 60 Freeway (Moreno Valley Freeway). The proposed offsite sewer would then extend under the 60 Freeway and continue southward along a proposed Eastern Municipal Water District (EMWD) easement to Eucalyptus Avenue where the proposed sewer would be tied-in to the existing sewer. The proposed offsite sewer extends approximately 3,500 feet from the Ironwood Avenue/Oliver Street intersection to Eucalyptus Avenue, including the 60 Freeway undercrossing. Based on a review of the sewer plans, it appears that the proposed offsite sewer will be 12-inches in diameter and composed of either PVC plastic or vitrified clay pipe (VCP).

For the proposed undercrossing of the 60 Freeway by the offsite sewer alignment, the bore and jack method will be utilized for the construction. Along the proposed sewer alignment immediately north of the 60 Freeway, a proposed 40-by 20-foot boring pit will be excavated to a depth of approximately 15 feet in order to accommodate horizontal drilling equipment. An approximately 15- by 20-foot receiving pit will be excavated to a depth of approximately 20 feet immediately adjacent to the south side of the 60 Freeway for the removal of drilling spoils. Once the pits are excavated and the drilling equipment is in place, a near horizontal boring will be drilled between the boring and receiving pits underneath the 60 Freeway and then shored with approximately 161 feet of 30-inch diameter steel casing. 189 feet of sewer pipe will then be placed through the steel casing and tied into the pipe sections on either side of the 60 Freeway. It appears that the depth from the surface to the top of the steel casing will vary from approximately 11 to 15 feet below existing grade. The drilling equipment will then be removed after pipe installation and the pits backfilled to complete the operation. The Client has requested that EEI conduct a Preliminary Geotechnical Evaluation of the subsurface conditions at the locations of the boring pit and receiving pit locations to determine the general subsurface conditions and the ease/difficulty of excavation at the pit locations.

1.3 Scope of Services

- Research of aerial photographs, readily available literature regarding local and regional geologic conditions, groundwater depth, fault rupture hazard zones and known fault locations, and other reasonably available geotechnical data or subsurface information relevant to the subject project(s).

- Conduct a geotechnical reconnaissance/site visit of the subject property(s) and nearby vicinity to mark boring locations for Underground Service Alert and to verify drilling rig access.

- Coordinate with Underground Service Alert to identify the presence of underground utilities for clearance of proposed boring and test pit locations.

- The drilling and logging of eight (8) small diameter exploratory borings (B-8 through B-15) in readily accessible areas of the subject property (Tract No. 31556) not previously investigated by EEI, ranging in depth from 15.5 to 42 feet below existing grade elevations (bgs).

- The drilling and logging of two (2) small diameter exploratory borings (B-16 and B-17) adjacent to each side of the proposed 60 Freeway undercrossing at the proposed bore and receiving pit locations for the Tract No. 31556 offsite sewer. Both borings were advanced to a depth of 21.5 feet below the existing grade elevations (bgs).

- The locations of the exploratory borings on the subject property (Tract No. 31556) are presented on **Figure 3** (Field Exploration Plan).

- The locations of each of the offsite exploratory borings (for the proposed offsite sewer boring and receiving pits) are presented on **Figure 4** (Offiste Sewer Boring Locations).
- An evaluation of seismicity and geologic hazards to include an evaluation of faulting.
- Completion of laboratory testing of representative earth materials encountered onsite to ascertain their pertinent soils engineering properties, including corrosion potential and excavation characteristics (**Appendix B**).
- The preparation of this report which presents our preliminary findings, conclusions, and recommendations for both the proposed Tract No. 31556 residential development and offsite sewer bore and receiving pit locations for the 60 Freeway undercrossing.

2.0 BACKGROUND

2.1 Subject Property Description

Based on the information provided by Anderson Consulting Engineers, Inc. ("Client"), and a review of the GoogleEarth© online database, and EEI's previous due diligence geotechnical evaluation, the subject property consists of approximately 80-acres of undeveloped vacant land (Tract No. 31556) located at the northwest corner of the intersection of Oliver Street and Ironwood Avenue, in the City of Moreno Valley, Riverside County, California. Nason Street forms the majority of the western boundary; Ironwood borders the south; and Oliver Street forms the eastern boundary. Vacant land is present to the north. In general, the area is characterized by rural residential and vacant land. Proposed development is for multi or single-family residential.

We understand that the proposed offsite sewer extends approximately 3,500 feet from the Ironwood Avenue/Oliver Street intersection (Tract No. 31556) to Eucalyptus Avenue, including the 60 Freeway undercrossing. Based on a review of the sewer plans, it appears that the proposed offsite sewer will be 12-inches in diameter and composed of either PVC plastic or vitrified clay pipe (VCP).

The subject property (Tract 31556) is approximately situated at 33.9448° north latitude and 117.1871° west longitude (GoogleEarth®, 2013).

2.2 Site Topography

A review of the Sunnymead, California 7.5-minute topographic quadrangle (USGS, 2012) and Project Exhibit/topographic map prepared by Anderson Consulting Engineers, Inc. indicates that the subject property (Tract No. 31556) elevation varies from approximately 1,840 to 1,980 feet above mean sea level (amsl). From east-west across the property is a series of north-south oriented ridges and alternating drainage gullies in the lower, southern portion of the property. The intervening ridges are generally about 5 to 10 feet higher in elevation than the adjacent drainage gullies. Rounded granitic outcrops are exposed in the northwestern and northeastern sections of the property. The property topography can be generally described as a relatively well-dissected alluvial fan descending from the eroded hills to the north. The overall surface gradient across the property is gently to moderately south or south-southeast.

2.3 Geologic Setting

The subject property and vicinity lies within the Peninsular Ranges Geomorphic Province of California (CGS, 2002). The Peninsular Ranges Geomorphic Province extends from the Transverse Ranges Geomorphic Province and the Los Angeles Basin, south to Baja California.

This province varies in width from about 30- to 100-miles. It is bounded on the west by the Pacific Ocean, on the south by the Gulf of California and on the east by the Colorado Desert Province. The Transverse Ranges Geomorphic Province bounds the Peninsular Ranges on the north. The Peninsular Ranges are essentially a series of northwest-southeast oriented fault blocks. Major fault zones and subordinate fault zones found in the Peninsular Ranges Province typically trend in a northwest-southeast direction.

Regional geologic maps of the subject property and vicinity (Morton et al., 2004) indicate the property is underlain by Cretaceous-age plutonic rocks composed of tonalite and Holocene age Younger Alluvial Fan deposits. Outcroppings of the weathered tonalite bedrock are exposed in the northwestern and northeastern portions of the property. Over the remainder of the property, the tonalite bedrock was found to be weathering into a soil with a "decomposed granite" or "dg" texture at depth in the exploratory borings in general is covered with several feet of alluvial and colluvial (younger alluvial fan) soils also derived from the weathered tonalite. The alluvial and colluvial soils are generally comprised of relatively loose to dense silty sand. The property is relatively undeveloped and artificial fill was not encountered during our field exploration at the property.

At the offsite sewer bore and receiving pit locations, several feet of artificial fill soils, likely associated with the construction of the 60 Freeway, were encountered at the surface and were underlain by alluvial soils to the maximum explored depth during our geotechnical evaluation.

Due to the proximity of the subject property area to several nearby active faults, strong ground shaking could occur at the property as a result of an earthquake on any one of the faults. Our review indicates that there are no known active faults crossing the property and the property is not within a State of California Earthquake Fault Zone (Jennings, 1994; Hart and Bryant, 1997, CDMG, 1974; 1998). Due to the presence of shallow bedrock and the lack of shallow groundwater at the property, the property is considered as having a low susceptibility to liquefaction.

2.4 Regional Groundwater

A seismic hazard zone map and report have not been completed for the Sunnymead Quadrangle, therefore, the depth to the historic high groundwater at the subject property is not known. Due to the presence of relatively shallow granitic bedrock at the property, static groundwater is not expected and groundwater was not encountered during our previous due diligence geotechnical evaluation or during our Supplementa; Geotechnical Evaluation to a maximum explored depth of 42 feet below the existing ground surface. Within the lower drainage gullies, up to 30 feet in thickness of silty sand alluvium was encountered. Although not encountered within the alluvium during our field excavation, during times of heavy precipitation or runoff, a localized perched groundwater condition could exist. A review of topographic maps of the general vicinity of the property indicates regional topographic relief slopes gently towards the south or south-southeast. This information suggests that regional groundwater in the property vicinity could be inferred to flow in the same general topographic direction.

3.0 FAULTING AND SEISMICITY

The portion of Southern California that includes the subject property is considered to be seismically active. Due to the proximity of the property area to several nearby active faults, strong ground shaking could occur at the property as a result of an earthquake on any one of the faults. Our review indicates that there are no known active faults crossing the property (Blake, 2000) and the property is not within an Earthquake Fault Zone (Hart and Bryant, 1997). It is our opinion, therefore, that the likelihood of surface fault rupture at the property is low. **Table 1** lists the major active faults within 25 miles that are likely to affect the property.

TABLE 1
Summary of Major Active Faults

	Fault Name	Approximate Distance From Site miles (kilometers)	Maximum Moment Magnitude
1	San Jacinto-San Jacinto Valley	1.5 (2.4)	6.9
2	San Jacinto-San Bernardino	5.8 (9.3)	6.7
3	San Andreas – San Bernardino M-1	12.1 (19.5)	7.5
4	San Andreas – SB-Coach. M-2b	12.1 (19.5)	7.7
5	San Andreas – SB-Coach. M-1b-2	12.1 (19.5)	7.7
6	San Andreas – Whole M-1a	12.1 (19.5)	8.0
7	North Frontal Fault Zone (West)	19.4 (31.2)	7.2
8	San Jacinto – Anza	21.0 (33.8)	7.2
9	Elsinore (Glen Ivy)	21.7 (35.0)	6.8
10	Cucamonga	21.9 (35.2)	6.9
11	Elsinore (Temecula)	22.8 (36.7)	6.8
12	Cleghorn	23.1 (37.2)	6.5
13	Chino-Central Ave. (Elsinore)	23.3 (37.5)	6.7

3.1 Seismic Parameters and Peak Ground Acceleration

Maximum considered ground motion maps provided in the California Building Code (CBC, 2013) were utilized with coordinates of 33.9448° north latitude and 117.1871° west longitude, to determine the subject property seismic parameters. EEI utilized seismic design criteria provided in the CBC (2013).

In accordance with the guidelines of the CBC (2013), the spectral parameters for the subject property (based on a Site Class B soil) are estimated to be S_s = 2.166g and S_1 = 0.982g. Review of the geotechnical data obtained during our subsurface exploration, however, indicates that the property should be classified as Class D per the CBC (Table 1613.5.2). Consequently, Site Coefficients F_a= 1.000 and F_v = 1.500 appear to be appropriate for the property. Based on this information, the adjusted maximum considered earthquake spectral response parameters S_{MS} = 2.166g and S_{M1} = 1.472g are recommended for seismic design of the project. Assuming an occupancy category of II (Table 1604A.5), an S_{DS} value of 1.444g and an S_{D1} value of 0.982g, the proposed building at the property can be assigned a seismic design category of D [Table 1613.5.6 (1) and (2)]. Final selection of the appropriate seismic design coefficients should be made by the structural consultant based on the local laws and ordinances, expected building response, and desired level of conservatism.

Seismic Hazard Response Parameters are listed in **Table 2**.

TABLE 2
Seismic Hazard Response Parameters and Design Parameters CBC (2013)

Latitude: 33.9448° - Longitude: -117.1871° Seismic Parameter	Period (Sec)		Value
Mapped Spectral Acceleration Value, Soil Class B	0.2	S_s	2.166g
Mapped Spectral Acceleration Value, Soil Class B	1.0	S_1	0.982g
Site Coefficient, Subject Site Soil Classification D per 2013 CBC Table 1613.5.2	--	F_a	1.000

3.2 Ground Lurching or Shallow Ground Rupture

Based on the geography, topography and site-specific geotechnical conditions encountered during our preliminary and Supplementa; Geotechnical Evaluations at the subject property, we consider the potential for ground lurching or shallow ground rupture at the property to be low; however, due to the active seismicity of California, this possibility cannot be completely ruled out. In light of this, the unlikely hazard of lurching or ground-rupture should not preclude consideration of "flexible" design for onsite utility lines and connections.

3.3 Liquefaction

Liquefaction is a phenomenon in which the strength and stiffness of a soil is reduced by earthquake shaking or other rapid loading. Liquefaction and related phenomena have been responsible for substantial structural damage in historical earthquakes, and are a design concern under certain conditions. Liquefaction occurs in saturated soils that are soils in which the space between individual particles is completely filled with water. This pore water exerts a pressure on the soil particles that influences how tightly the particles themselves are pressed together.

Prior to an earthquake, pore water pressure is typically low; however, earthquake motion can cause the pore water pressure to increase to the point where the soil particles can readily move with respect to each other. When liquefaction occurs; the strength of the soil decreases and the ability of a soil deposit to support structural loads are reduced.

A seismic hazard zone map and report for the Sunnymead Quadrangle has not been issued by the California Geological Survey (CGS) so the subject property is, therefore, not situated within a mapped Liquefaction Zone. The lower elevation portions of the property is generally underlain by generally loose to medium dense alluvial and colluvial deposits that overlie relatively shallow granitic bedrock while the upper elevation portions of the site are generally underlain by dense to very dense alluvial and colluvial deposits over granitic bedrock. The alluvial and colluvial soils are subject to partial and/or complete removal and recompaction during site grading for the proposed residential development. It appears that liquefaction is not a significant geotechnical concern at the property.

Cyclic mobility is a liquefaction phenomenon, triggered by cyclic loading, occurring in soil deposits with static shear stresses lower than the soil strength. Deformations due to cyclic mobility develop incrementally because of static and dynamic stresses that exist during an earthquake. Lateral spreading, a common result of cyclic mobility, can occur on gently sloping and on flat ground close to rivers and lakes. These conditions do exist within the subject property, however, based on the conceptual site plan, the property should be relatively level following rough grading with a lack of free channel faces and cyclic mobility should not be an issue post-grading.

3.4 Seismic Induced Settlement

Seismically induced settlement can occur due to reorientation of soil particles during strong shaking of unsaturated sands, as well as in response to liquefaction of saturated loose granular soils.

Based on our evaluation and the geotechnical data obtained from our exploratory borings, we estimate the total seismic-induced settlement to be less than 1-inch. Differential earthquake induced settlements are estimated to be less than 0.5-inches over a 50-foot span.

4.0 FIELD EXPLORATION AND LABORATORY TESTING

4.1 Field Exploration

Fieldwork for our geotechnical evaluation was conducted on April 16 and 17, 2015. The drilling and logging of eight (8) small diameter exploratory borings (B-8 through B-15) in readily accessible areas of the subject property (Tract No. 31556) not previously investigated by EEI, ranging in depth from 15.5 to 42 feet below existing grade elevations (bgs). Additionally, drilling and logging of two (2) small diameter exploratory borings (B-16 and B-17) was completed adjacent to each side of the proposed 60 Freeway undercrossing at the proposed bore and receiving pit locations for Tract No. 31556 offsite sewer. Both borings were advanced to a depth of 21.5 feet below the existing grade elevations (bgs). All exploratory borings were logged under the supervision of a Registered Professional Engineer and/or Certified Engineering Geologist at EEI. Boring locations were adjusted as necessary due to existing utilities and improvements.

Blow count (N) values were determined utilizing a 140-pound automatic hammer, falling 30-inches onto a Standard Penetration Test (SPT) split-spoon sampler and a Modified California split-tube sampler. A truck mounted hollow-stem auger (HSA) drill rig was used during fieldwork. The blows per foot (N value) required to advance the 18-inch long SPT and 12-inch long Modified California split-tube samplers was measured at various initial depths followed by 5-foot intervals, recorded on the boring logs. The boring logs for the field exploration are presented in **Appendix A**-Soil Classification Chart and Boring & Trench Logs. Relatively "undisturbed" samples were collected in a 2.42-inch (inside diameter) California Modified split-tube sampler for visual examination and laboratory testing in the exploratory borings. The soils were classified in accordance with the Unified Soil Classification System (ASTM, 2008). Representative bulk samples were also collected from the exploratory borings for appropriate laboratory testing.

4.2 Subsurface Conditions

The results of our geotechnical exploration indicate that the proposed residential development is underlain by weathered Cretaceous-age plutonic rocks composed of tonalite. This material was observed to extend beyond the maximum depth of our exploratory borings (approximately 42 feet below existing grades). Alluvial soils up to 30 feet thick were observed to mantle the weathered tonalite bedrock within the lower lying channel/drainage areas during our previous geotechnical site evaluation and were not penetrated during our maximum explored depth during our supplemental evaluation.

On the higher, elevated ridge areas on the subject property, colluvial soils were observed to mantle the weathered tonalite bedrock with a thickness varying between 2 and 21.5 feet (similar to the 3 to 14 feet encountered during due diligence evaluation). The weathered tonalite bedrock can generally be described as gray, white or black speckled or orange to dark grayish-orange (depending on degree of weathering) with a "granitic" or phaneritic texture and was generally unweathered to highly weathered. Outcroppings of the weathered tonalite bedrock are exposed in the northwestern and northeastern portions of the site. Over the remainder of the property, the tonalite bedrock was found to be weathering into a medium dense to very dense silty sand soil with a "decomposed granite" or "dg" texture at depth in the exploratory borings and test pits. The alluvial and colluvial (younger alluvial fan) soils are also derived from the weathered tonalite.

The alluvial and colluvial soils are generally comprised of orange-brown mottled or light brown, fine to coarse, damp to moist, loose to dense silty sand and gravelly sand. The property is relatively undeveloped and artificial fill was not encountered during our field exploration at the property.

Our exploratory excavations were performed utilizing light-duty equipment, which can provide general excavation characteristics of the onsite materials. Large granitic (tonalite) bedrock outcrops are present on the northeast and northwest portions of the property, along with some isolated rock outcrops within the areas of the proposed development area and generally on the higher elevations of the property. Boulders were present at the surface in these areas, some localized "core rock or floaters" should be anticipated at variable depths in these areas. Based on observed subsurface conditions in the exploratory borings, the "decomposed granite" or "dg" is moderately to highly weathered and/or fractured and was relatively easy to excavate to the depths indicated with a drill rig equipped with flight auger equipment. Refusal was encountered at a depth of 42 feet bgs in exploratory boring B-8 during our field exploration.

In general, the ease of rock excavation or rippability depends on various factors such as rock type, rock hardness and density, the amount of weathering, and the existence and characteristics of discontinuities such as joint spacing, foliation, or fractures.

Due to the relatively dense character of the granitic bedrock encountered onsite, it is likely that oversized rock materials will be created during grading operations. Native earth materials appear to be suitable for use as structural fill provided they are moisture conditioned (as needed), meet EEI's recommendations for size and are properly compacted. Dependent upon the grading plan, some of the oversized materials may be re-used in landscape areas.

For the proposed offsite sewer bore pit and receiving pit locations, alluvial soils at depth were overlain by artificial fill soils from the surface to a depth of approximately 11 feet bgs in exploratory boring B-16 and a depth of approximately 16 feet bgs in exploratory boring B-17. Alluvial soils were then encountered below the artificial fill to the maximum explored depth of 21.5 feet bgs. The offsite alluvial soils can generally be described as light brown to brown, fine to medium, moist, medium dense silty sand. The artificial fill soils encountered can be described as brown, red-brown or dark orange-brown, fine to coarse, damp to moist, loose to medium dense silty sand and sandy silt. Refusal was not encountered within either of our offsite exploratory borings. Detailed descriptions of the encountered soils are provided on the boring logs and test pit logs included as **Appendix A**.

Due to the presence of relatively shallow granitic bedrock at subject property, static groundwater is not expected and groundwater was not encountered in any of the exploratory borings excavated at the property to a maximum explored depth of 42 feet below the existing ground surface. Our review of ground water monitoring data from nearby wells suggests that the groundwater level may fluctuate seasonally and yearly.

It should be noted that fluctuations in the ground water level could also occur due to variations in ground surface topography, subsurface stratifications, precipitation, irrigation, and other factors which may not have been evident at the time of our exploration.

4.3 Laboratory Testing and Classification

Representative samples were selected for laboratory testing to confirm their field classification(s). Field descriptions and classifications were visually classified according to the American Society for Testing and Materials (ASTM) D2488 which classifies soils under the Unified Soil Classification System (USCS). Representative soil samples were tested in the lab for grain size distribution, liquid limits, and plastic limits to determine actual classifications by ASTM D2487-Standard Practice for Classification of Soils for Engineering Purposes in accordance to the USCS. Final classifications of soils can be found on the boring logs in **Appendix A** and the laboratory test data in **Appendix B**.

4.3.1 Moisture Content and Dry Density

The in-situ moisture content and dry density of soils were determined for soil samples obtained from the borings. Moisture contents and dry densities of soils help to determine engineering design parameters for foundations, retaining walls, and other engineered structures. Moisture content on soil samples was conducted in general accordance with ASTM D2216, and was recorded as a percentage. In-situ moisture content and dry density information for soil samples retrieved from the field can be found on the boring logs located in **Appendix A**.

4.3.2 Grain Size Distribution

To help check field classifications of soils, the grain size distribution of representative soil samples was determined. In order to find the percentages of different sized particles in a particular soil stratum, soils were tested in general accordance with ASTM D422-Standard Test Method for Particle-Size Analysis of Soils. Grain size distribution curves and gradation results are presented in **Appendix B.**

4.3.3 Maximum Dry Density and Optimum Moisture Content

The maximum dry density and optimum moisture content were determined from a bulk sample obtained from boring B-8 at depths between 0 and 5 feet below existing grade. Our testing was performed in general accordance with ASTM D1557, Method A. Results of our testing are presented in **Appendix B**.

4.3.4 Expansion Index

A soil sample from boring B-8 within the upper 5 feet of existing grade was tested for its expansion potential. Our expansion index testing was conducted in general accordance with ASTM D4829. The results of our expansion index testing are presented in **Appendix B.**

4.3.5 Sulfate/Corrosion

One representative sample of onsite earth material was collected for analysis at Clarkson Laboratory and Supply, Inc. located in Chula Vista, California for corrosion/soluble sulfate potential. This corrosion testing included soil minimum resistivity and pH by California Test 643, sulfate by California Test 417, and chloride by California Test 422. Results of these tests are presented in **Appendix B**.

It should be understood that the results provided in **Appendix B** are based upon pre-development conditions. Verification testing is recommended at the conclusion of grading on samples collected at or near finish grade.

5.0 CONCLUSIONS

Based on our field exploration, laboratory testing and engineering and geologic analysis, it is our opinion that the subject property is suitable for the proposed new development and associated improvements from a geotechnical engineering and geologic viewpoint; however, there are existing geotechnical conditions associated with the property that will warrant mitigation and/or consideration during planning stages. If site plans and/or the location of the proposed residential buildings or proposed offsite sewer bore and receiving pit locations are revised, additional field studies may be warranted to address proposed site-specific conditions.

In general, based on the results of EEI's supplemental investigation, conclusions are generally unchanged from those presented in our previous due diligence geotechnical report, dated November 25, 2014. As a result, EEI is providing the following conclusions:

- A total of eight (8) hollow stem auger borings were drilled on the subject property (Tract No. 31556). Boring depths ranged from 15.5 to 42 feet below the existing ground surface. Two (2) additional hollow stem auger borings were drilled offsite in the area of the proposed Tract No. 31556 offsite sewer line undercrossing of Freeway 60. Both of these borings were drilled to an approximate depth of 21.5 feet below existing grade. The results of our geotechnical exploration indicate that the subject property development is underlain by weathered Cretaceous-age plutonic rocks composed of tonalite. This material was observed to extend beyond the maximum depth of our exploratory borings (approximately 42 feet below existing grades). Alluvial soils up to 30 feet thick were observed to mantle the weathered tonalite bedrock within the lower lying channel/drainage areas during our previous geotechnical site evaluation and were not penetrated during our maximum explored depth during our supplemental evaluation.

- On the higher, elevated ridge areas on the subject property, colluvial soils were observed to mantle the weathered tonalite bedrock with a thickness varying between 2 and 21.5 feet (similar to the 3 to 14 feet encountered during due diligence evaluation). The weathered tonalite bedrock can generally be described as gray, white or black speckled or orange to dark grayish-orange (depending on degree of weathering) with a "granitic" or phaneritic texture and was generally unweathered to highly weathered. Outcroppings of the weathered tonalite bedrock are exposed in the northwestern and northeastern portions of the property. Over the remainder of the property, the tonalite bedrock was found to be weathering into a medium dense to very dense silty sand soil with a "decomposed granite" or "dg" texture at depth in the exploratory borings and test pits. The alluvial and colluvial (younger alluvial fan) soils are also derived from the weathered tonalite. The alluvial and colluvial soils are generally comprised of orange-brown mottled or light brown, fine to coarse, damp to moist, loose to dense silty sand and gravelly sand. Refusal was encountered at a depth of 42 feet bgs in exploratory boring B-8 during our field exploration.

- For the proposed offsite sewer bore pit and receiving pit locations, alluvial soils at depth were overlain by artificial fill soils from the surface to a depth of approximately 11 feet bgs in exploratory boring B-16 and a depth of approximately 16 feet bgs in exploratory boring B-17. Alluvial soils were then encountered below the artificial fill to the maximum explored depth of 21.5 feet bgs. The offsite alluvial soils can generally be described as light brown to brown, fine to medium, moist, medium dense silty sand. The artificial fill soils encountered can be described as brown, red-brown or dark orange-brown, fine to coarse, damp to moist, loose to medium dense silty sand and sandy silt. Refusal was not encountered within either of our offsite exploratory borings.

- Groundwater was not encountered in any of our onsite or offsite exploratory borings to the depths explored (approximately 42 feet below existing grades). It should be noted that variations in groundwater may result from fluctuations in the ground surface topography, subsurface stratification, precipitation, irrigation and other factors that may not have been evident at the time of our subsurface exploration.

- Laboratory test results indicate that the near surface materials are mildly alkaline (pH = 7.4) and are corrosive to ferrous metals with a minimum resistivity value of 3,500 ohm-cm. Laboratory testing of the upper soils yielded a soluble sulfate concentration of 0.003 percent and a chloride concentration of 0.001 percent, indicating a negligible corrosion potential to reinforced concrete.

- The results of our laboratory Expansion Index (EI) testing indicate an Expansion Index of 2, for the tested soils which represents a very low expansion potential.

- The subject property is located within an area of Southern California recognized as having a number of active and potentially active faults. Our review indicates that there are no known active faults crossing the property and the property is not located within an Earthquake Fault Zone. The nearest active faults that could affect the property are the San Jacinto Valley segment of the San Jacinto Fault Zone, located approximately 1.5 miles from the property, the San Bernardino segment of the San Jacinto Fault Zone, located approximately 5.8 miles from the area of study, the San Bernardino M-1 segment of the San Andreas Fault Zone, the San Bernardino-Coachella Valley M-2b segment of the San Andreas Fault Zone, the San Bernardino-Coachella Valley M-1b-2 segment of the San Andreas Fault Zone and the San Bernardino-Coachella Valley M-1a segment of the San Andreas Fault Zone, all located approximately 12.1 miles from the area of study. Each of these active faults is capable of generating severe ground shaking at the property. A list of active faults within an approximate 25-mile radius is presented in **Table 1**.

- Based on EEI's evaluation, earth materials underlying the subject property are not considered susceptible to liquefaction or significant amounts of seismic settlement. Based on EEI's evaluation, the earth materials underlying the property of the proposed development appear to be susceptible to some seismically induced settlement on the order of less than one-inch with differential settlements of less than 0.5-inches over a 50-foot span. Liquefaction-induced lateral spreading does not appear to be a concern at the property due to the lack of shallow groundwater, the lack of nearby open face channels and the relatively shallow depth to bedrock.

- At this time we cannot present specific footing recommendations that can be incorporated in the structural design, given that we do not have a scope of the proposed project, no grading or foundation plans were available at the time and no information was provided to us other than the Client is considering purchasing the property for future development.

6.0 RECOMMENDATIONS

The recommendations presented herein should be considered as preliminary for the purpose of characterizing the geotechnical and geologic conditions at the subject property prior to purchasing the property, and for preliminary information to aid the initial planning and design phases of development. Guidelines for site preparation, earthwork, and onsite improvements were previously provided in the Due Diligence Level Geotechnical Evaluation report by EEI dated November 25, 2014. Based on the results of our Supplemental Geotechnical Evaluation of the subject property, the following recommendations as presented are essentially unchanged from the 2014 EEI report, except where specifically discussed. The subsurface conditions encountered at the additional boring locations verified the subsurface conditions encountered in the 2014 exploratory borings and test pits and therefore, has verified the recommendations and conclusions of the earlier referenced EEI report, except where specifically discussed due to a change in subsurface conditions from the previous EEI report.

Our assumption is also that the onsite development will still consist of single-family, wood-frame, slab-on-grade 1- to 2-story residential structures and the planned offsite construction for the proposed sewer line including the bore-and-jack method for the 60 Freeway undercrossing of the sewer line.

6.1 General

Grading should conform to the guidelines presented in the 2013 California Building Code (CBC, 2013), as well as the requirements of the City of Moreno Valley and the County of Riverside. Additionally, general Earthwork and Grading Guidelines are provided herein as **Appendix C**.

During earthwork construction, removals and reprocessing of fill materials, as well as general grading procedures of the contractor should be observed and the fill placed selectively tested by representatives of the geotechnical engineer, EEI. If any unusual or unexpected conditions are exposed in the field, they should be reviewed by the Geotechnical Engineer and if warranted, modified and/or additional remedial recommendations will be offered. Specific guidelines and comments pertinent to the planned development are provided herein.

The recommendations presented herein have been completed using the preliminary information provided to us regarding site development. If information concerning the proposed development is revised, or any changes in the design and location of the proposed property improvements are made, the preliminary conclusions and recommendations contained in this report should not be considered applicable unless the changes are reviewed and conclusions of this report modified or approved in writing by this office.

6.2 Site Preparation and Grading

Debris and other deleterious material, such as organic soils and/or environmentally impacted earth materials should be removed from the subject property prior to the start of grading. Areas to receive fill should be properly benched in accordance with current industry standards of practice and guidelines specified in the CBC and the requirements of the local jurisdiction.

Existing utilities should be removed within the proposed building envelope. Abandoned trenches should be properly backfilled and tested. If unanticipated subsurface improvements (utility lines, septic systems, wells, utilities, etc.) are encountered during earthwork construction, the geotechnical engineer should be informed and appropriate remedial recommendations would then be provided.

6.3 Remedial Earthwork

The encountered portions of the existing surficial soils including the upper portions of the alluvial and colluvial soils were observed to be somewhat loose and variable in moisture content and relative density. As such, they are considered potentially compressible and unsuitable for the support of settlement-sensitive structures or engineered fill in their current condition. Therefore, where not already removed by the proposed site grading, the existing native materials should be completely removed and recompacted in the areas to receive the proposed building improvement and other settlement-sensitive improvements within some of the lower elevation portions of the property. Based on the results of our subsurface exploration, we recommend that these removals extend to approximate depths on the order of a minimum of 4 feet to a maximum of 30 feet below the existing ground surface, or 24-inches below the bottoms of the proposed foundations. At the approximate location of boring B-1, 30 feet of relatively loose to medium dense silty sand alluvium was encountered above the tonalite bedrock and should be removed to a depth of 30 feet. A similar situation likely exists in other, lower elevation portions of the property within the drainage channels. In the upper elevation portions of the property, alluvial and colluvial soils tend to be dense to very dense and relatively well cemented, will likely require a minimum depth of removal and recompaction, and will generally not require complete removal and recompaction to the granitic bedrock. Once grading plans become available to EEI or review, the estimated removal depth of the native materials at the property can be approximately determined and provided.

Following removal of the upper soils, the bottom of the resulting excavation(s) should be observed by a representative of EEI to check that unsuitable materials have been sufficiently removed. It should be understood that based on the observations of our field representative, localized deeper removals may be recommended. The base of the removal area should be level to avoid differential fill thicknesses under proposed improvements. This remedial earthwork should extend at least 5 feet outside the proposed building limits and/or 5 feet beyond the area to receive fill. Note that vertical sides exceeding 5 feet in depth may be prone to sloughing and may require laying back to an inclination of 1:1 (horizontal to vertical).

After removal of the upper soils and observation of the excavation bottoms, the over-excavated areas should be scarified to a minimum depth of 6-inches, moisture conditioned as needed to achieve at least optimum moisture content and re-compacted to at least 90 percent of the maximum dry density (based on ASTM D1557). The over-excavated areas should then be backfilled with onsite and/or imported soils that are placed and compacted as recommended herein until design finish grades are reached.

6.4 Fill Placement

Fill material should possess a very low expansion potential (expansion index of less than 21 as determined by ASTM D4829), be free of organic matter (less than 3 percent organics by weight) and other deleterious material. Much of the onsite materials appear to be suitable for re-use as fill, provided they do not contain rocks greater than 6-inches in maximum dimension, organic debris and other deleterious materials. Rock fragments exceeding 6-inches in one dimension should be segregated and exported from the subject property, or utilized for landscaping.

If import soils are needed, the earthwork contractor should ensure that all proposed fill materials are approved by the geotechnical engineer prior to use. Representative soil samples should be made available for testing at least ten working days prior to hauling to the subject property to allow for laboratory tests.

Fill materials should be placed in 6- to 8-inch loose lifts, moisture conditioned as necessary to at least optimum moisture and compacted to a minimum of 90 percent maximum dry density according to ASTM D1557. The upper 12-inches of pavement subgrade should be moisture conditioned to at least optimum moisture and compacted to at least 95 percent of the maximum dry density as determined by ASTM D1557. Suitable heavy grading equipment should be utilized to properly mix, spread, moisture condition or dry, and compact each fill lift.

Earthwork may be affected by the existing soil moisture content exceeding optimum. Moist to very moist earth materials may be difficult to mix and compact in their native condition, and drying or mixing with drier soils may be warranted to achieve the recommended relative compaction.

Those areas to receive fill (including over-excavated areas) or surface improvements should be scarified at least 12-inches, moisture conditioned to at least optimum moisture content and recompacted to at least 90 percent of the maximum dry density (based on ASTM D1557).

6.5 Yielding Subgrade Conditions

The soils encountered at the subject property can often exhibit "pumping" or yielding once they become saturated. This can often occur in response to periods of significant precipitation, such as during the winter rainy season. If this occurs and in order to help stabilize the yielding subgrade soils within the bottom of the removal areas, the contractor can consider as an option, the placement of uniform sized, ¾- to 2-inch crushed rock within areas exhibiting the "pumping" conditions. The crushed rock should be properly tracked into the underlying soils such that it is adequately intruded into and interlocks with the soils. We expect that a 6- to 12-inch thick section of the crushed rock will be required.

Following the placement and tracking of the gravel layer into the underlying "pumping" soils, it is recommended that Mirafi 600X stabilization fabric (or approved equivalent) then be placed upon the gravel layer. Fill soils, which should be placed and compacted in accordance with the recommendations presented herein, should then be placed upon the fabric until design finish grades are reached. The gravel and stabilization fabric should extend at least 5 feet laterally beyond the limits of the "pumping" areas. These operations should be performed under the observation and testing of a representative of EEI in order to evaluate the effectiveness of these measures and to provide additional recommendations for mitigative measures, as warranted.

6.6 Shrinkage and Bulking

Several factors will affect earthwork balancing on the subject property, including shrinkage, bulking, subsidence, trench spoils from utilities and footing excavations, and final pavement section thickness as well as the accuracy of topography.

Shrinkage, bulking and subsidence are primarily dependent upon the degree of compactive effort achieved during construction. For planning purposes, the shrinkage factor is estimated to be about 10 to 15 percent for the onsite natural soils to be utilized as fill. This shrinkage factor may vary with methods employed by the contractor. Subsidence is estimated to be about 0.1 feet. For preliminary planning purposes, bulking of the granitic bedrock derived materials is estimated to be 0 to 10 percent. Losses from site clearing and removal of existing site improvements as well as generation of oversize material may affect earthwork quantity calculation and should be considered.

The previous estimates are intended as an aid for the project engineers in estimating earthwork quantities. It is recommended that the site development be planned to include an area that could be raised or lowered to accommodate final site balancing.

Several factors will affect earthwork balancing on the subject property, including shrinkage, bulking, subsidence, trench spoils from utilities and footing excavations, and final pavement section thickness as well as the accuracy of topography

7.0 PRELIMNARY FOUNDATION RECOMMENDATIONS

7.1 General

The conclusions and recommendations presented herein are based on the assumption that the planned development will consist of two- to four-story wood frame residential structures with slab-on-grade. It is our understanding that these conceptual plans are also part of the due diligence phase of the project and may or may not be the final design. As such, the conclusions and recommendations contained in this Supplemental Geotechnical Evaluation report should be considered preliminary, and should be reviewed, revised and/or approved in writing by EEI at the time the project design is finalized.

Be advised that as part of the foundation design election process, there is always a cost/benefit evaluation. Although we are providing alternatives for foundation design, we have not accomplished the cost/benefit evaluation.

7.2 Preliminary Foundation Design

Lightly loaded wood-frame, two- to four-story residential buildings with a slab-on-grade, can be supported on conventional continuous or isolated spread footings bearing upon at least 24-inches of properly compacted fill materials.

In preparation for foundation construction, the earthwork contractor should ensure that the site has been prepared as recommended, and that field density tests have been performed to adequately document the relative compaction of the structural fill.

Conventional foundations can be designed to impose dead plus long term live load bearing pressures of 2,000 pounds per square foot (psf). The allowable foundation bearing pressure is for footings having a minimum width of 15-inches and a minimum depth of 18-inches embedment below the lowest adjacent finish grade for one or two story buildings and 18-inches wide and a minimum 24-inches embedment below lowest adjacent finish grade for three or four-story buildings. The allowable soil bearing pressure can be increased by one-third when considering transient loads of short duration, such as wind or earthquake loads. Based on the prevailing geotechnical conditions encountered during our subsurface exploration, we recommend that foundations be reinforced with at least two No. 4 bars placed at the top of the footing and two placed at the bottom.

Horizontal loads acting on foundations and stem walls cast in open excavations against undisturbed native soil or against properly placed and compacted fill will be resisted by friction acting along the base of the footing and by passive earth pressures against the side of the footing and stem wall. The frictional resistance acting along the base of footings founded on suitable foundation soils may be computed using a coefficient of friction equal to 0.30 with the normal dead load.

Passive earth pressures acting against the side of footings and stem walls may be assumed to be equivalent to a fluid weighing 250 pounds per cubic foot. Passive pressure in the upper 1.0-foot should be neglected unless confined by concrete slabs-on-grade or asphalt concrete pavement. The values given above may be increased by one-third for transient wind or seismic loads.

7.3 Footing Setbacks

All footings should maintain a minimum 7-foot horizontal setback from the base of the footing to any descending slope (if existing onsite). This distance is measured from the outside footing face at the bearing elevation. Footings should maintain a minimum horizontal setback of H/3 (H=slope height) from the base of the footing to the descending slope face and no less than 7 feet, or greater than 40 feet.

Footings adjacent to unlined drainage swales or underground utilities (if any) should be deepened to a minimum of 6-inches below the invert of the adjacent unlined swale or utilities. This distance is measured from the footing face at the bearing elevation. Footings for structures adjacent to retaining walls should be deepened so as to extend below a 1:1 projection from the heel of the wall. Alternatively, walls may be designed to accommodate structural loads from buildings or appurtenances.

7.4 Construction

The foundation construction considerations contained herein are presented as minimum preliminary recommendations from a soils engineering standpoint. Laboratory test results indicate the onsite soils' swell (expansion) potential is very low. During grading of the site, we recommend that no soil possessing an Expansion Index of more than 20 be placed within 18-inches of finish grade, if possible. As such, design parameters provided herein assume that finish grade soil materials will have a low expansion potential.

Recommendations by the project's design-structural engineer or architect, which may exceed the soils engineer's recommendations, should take precedence over the following minimum preliminary considerations. Final foundation design should be provided based on the expansion potential of the near surface soils encountered during grading.

7.5 Concrete Slab-on-Grade

Interior slabs can be grade supported by structural fill whose placement/compaction is documented by the project soils engineer/engineer geologist as recommended herein. The thickness of the slab should be in accordance with the structural engineer's design. However, based on geotechnical considerations, we recommend that concrete slabs be a minimum of 4-inches in thickness. Concrete slabs should be underlain by at least 2-inches of clean sand with a Sand Equivalent (SE) of at least 30. Where moisture condensation is undesirable, concrete slabs should be underlain with a moisture/vapor retarder consisting of a minimum 10-mil, visqueen membrane, with all laps sealed. The membrane should be underlain by a 2-inch layer of clean sand with the aforementioned sand layer placed over the visqueen to aid concrete curing. To reduce the potential for buildup of hydrostatic pressures, the free draining material under the slabs should have positive drainage with no low lying areas (i.e., depressions) created.

Floor slabs should be suitably reinforced and jointed (in accordance with Structural Engineer's recommendations) so that a small amount of independent movement can occur without causing damage. Based on the encountered geotechnical conditions, we recommend that floor slabs be reinforced with No. 4 bars spaced on 18-inch centers (each way)

The contractor should take the appropriate precautions to make sure that the reinforcement is placed and maintained within the middle one-third of the slab. Exterior slabs, such as walkways and driveways, can be adequately supported on documented structural fill that is at minimum 12-inches in thickness, and placed and compacted in accordance with the recommendations contained herein.

In preparation for slab or flatwork construction, the earthwork contractor should ensure that the onsite soils have been prepared as recommended and that field density tests have been performed to adequately document the relative compaction of the structural fill. Preparation of the native soils should be documented prior to placement of aggregate, structural components and/or fill.

Some minor cracking of slabs can be expected due to shrinkage. The potential for this slab cracking can be reduced by careful control of water/cement ratios in the concrete. The contractor should take appropriate curing precautions during the pouring of concrete in hot or windy weather to reduce the potential for cracking of slabs. We recommend that a slipsheet (or equivalent) be utilized if grouted fill, tile, or other crack-sensitive floor covering is planned directly on concrete slabs. All slabs should be designed in accordance with structural considerations.

All dedicated exterior flatwork should conform to standards provided by the governing agency including section composition, supporting material thickness and any requirements for reinforcing steel. Concrete mix proportions and construction techniques, including the addition of water and improper curing, can adversely affect the finished quality of the concrete and result in cracking and spalling of the slab. We recommend that all placement and curing be performed in accordance with procedures outlined by the American Concrete Institute and/or Portland Cement Association. Special consideration should be given to concrete placed and cured during hot or cold weather conditions. Proper control joints should be provided to reduce the potential for damage resulting from shrinkage.

Laboratory test results indicate that the upper soils contain soluble sulfate concentrations of 0.003 percent and chloride concentrations of 0.001 percent. The results of these analyses indicate a negligible corrosion potential to concrete. As such, Type II cement can be used in concrete elements that will be in contact with the upper soils.

8.0 PAVEMENT DESIGN RECOMMENDATIONS

Deleterious material, excessively wet or dry pockets, concentrated zones of oversized rock fragments, and any other unsuitable yielding materials encountered during grading should be removed. Once compacted fill and/or native soils are brought to the proposed pavement subgrade elevations, the subgrade should be proof-rolled in order to check for a uniform firm and unyielding surface. Representatives of the project geotechnical engineer should observe all grading and fill placement.

The upper 12-inches of pavement subgrade soils should be scarified; moisture conditioned to at least optimum moisture content and compacted to at least 95 percent of the laboratory standard (ASTM D1557). If loose or yielding materials are encountered during subgrade preparation, evaluation should be performed by EEI. Aggregate base materials should be properly prepared (i.e., processed and moisture conditioned) and compacted to at least 95 percent of the maximum dry density as determined by ASTM D1557. Aggregate base materials should conform to Caltrans specifications for Class 2 aggregate base.

All pavement section changes should be properly transitioned. Although not anticipated, if adverse conditions are encountered during the preparation of subgrade materials, special construction methods may need to be employed. A representative of the project geotechnical engineer should be present for the preparation of subgrade and aggregate base.

For design purposes, we have assumed a Traffic Index (TI) of 4.5 for the proposed parking areas and 6.0 for drive areas at the subject property. These assumed TI's should be verified as necessary by the Civil Engineer or Traffic Engineer. For preliminary design purposes, we have conservatively assumed a preliminary R-Value of 20 for the materials likely to be exposed at subgrade. The modulus of subgrade reaction (K-Value) was estimated at 70 pounds per square inch per inch (psi/in) for an R-Value of 20 (Caltrans, 1974).

TABLE 3
Preliminary Pavement Design Recommendations

Traffic Index (TI)	Pavement Surface	Aggregate Base Material (1)
4.5 – Parking Stalls	3.0-inches Asphalt Concrete	6.0-inches
6.0 – Main Drive Areas	4.0-inches Asphalt Concrete	8.0-inches
Trash Area and Concrete Pavement	5.5-inches Portland Cement Concrete (2)	Optional

(1) R-Value of 78 for Caltrans Class 2 aggregate base
(2) Reinforcement and control joints placed in accordance with the structural engineer's requirements

The recommended pavement sections provided above are intended as a preliminary minimum guideline. If thinner or highly variable pavement sections are constructed, increased maintenance and repair could be expected. If the ADT (average daily traffic) or ADTT (average daily truck traffic) increases beyond that intended, as reflected by the assumed traffic index used for design, increased maintenance and repair could be required for the pavement section. Final pavement design should be verified by testing of soils exposed at subgrade after grading has been completed. Thicker pavement sections could result if R-Value testing indicates lower values.

9.0 DEVELOPMENT RECOMMENDATIONS

9.1 Landscape Maintenance and Planting

Water is known to decrease the physical strength of earth materials, significantly reducing stability by high moisture conditions. Surface drainage away from foundations and graded slopes should be maintained. Only the volume and frequency of irrigation necessary to sustain plant life should be applied.

Consideration should be given to selecting lightweight, deep rooted types of landscape vegetation which require low irrigation that are capable of surviving the local climate. From a soils engineering viewpoint, "leaching" of the onsite soils is not recommended for establishing landscaping. If landscape soils are processed for the addition of amendments, the processed soils should be re-compacted to at least 90 percent relative compaction (based on ASTM D1557).

9.2 Site Drainage

Positive site drainage should be maintained at all times. Drainage should not flow uncontrolled over slopes or the subject property. Runoff should be channeled away from slopes and structures and not allowed to pond and/or seep uncontrolled into the ground. Pad drainage should be directed toward an acceptable outlet. Although not required, roof gutters and down spouts may be considered to control roof drainage, discharging a minimum of 10 feet from the proposed structures, or into a subsurface drainage system. Consideration should be given to eliminating open bottom planters directly adjacent to proposed structures for a minimum distance of 10 feet. As an alternative, closed-bottom type planters could be utilized, with a properly designed drain outlet placed in the bottom of the planter.

9.3 Stormwater Disposal Systems

EEI understands that current plans call for runoff generated from the facility to be disposed of in engineered subsurface features onsite. Percolation testing was conducted at three widely separated locations for proposed onsite detention basins during our Due Diligence Level Geotechnical Evaluation performed in 2014 and the percolation testing results are presented in the referenced report by EEI dated November 25, 2014.

9.4 Additional Site Improvements

Recommendations for additional grading, exterior concrete flatwork design and construction can be provided upon request. If in the future, additional property improvements are planned for the subject property, recommendations concerning the design and construction of improvements would be provided upon request.

9.5 Trenching

All temporary excavations for grading purposes and installation of underground utilities should be constructed in accordance with OSHA guidelines and local safety codes. Temporary excavations over 5 feet in height should be evaluated by the project engineer, and could require shoring, sloping, or a combination thereof. Temporary excavations within the onsite materials should be stable at 1:1 inclinations for cuts less than 10 feet in height.

Footing trench excavations for structures and walls should be observed and approved by a representative of the project soils engineer prior to placing reinforcement. Footing trench spoil and excess soils generated from utility trench excavations should be compacted to a minimum relative compaction of 90 percent (based on ASTM D1557) if not removed from the subject property. All excavations should conform to OSHA and local safety codes.

9.6 Utility Backfill

Fill around the pipe should be placed in accordance with details shown on the drawings, and should be placed in layers not to exceed 8-inches loose (unless otherwise approved by the geotechnical engineer) and compacted to at least 90 percent of the maximum dry density as determined in accordance with ASTM D1557 (Modified Proctor). The geotechnical engineer should approve all backfill material. Select material should be used when called for on the drawings, or when recommended by the geotechnical engineer. Care should be taken during backfill and compaction operations to maintain alignment and prevent damage to the joints. The backfill should be kept free from oversized material, chunks of highly plastic clay, or other objectionable material. Backfill soils should be non-expansive, non-corrosive, and compatible with native earth materials. Backfill materials and testing should be in accordance with the CBC (2013), and the requirements of the local governing jurisdiction.

Pipe backfill areas should be graded and maintained in such a condition that erosion or saturation will not damage the pipe bed or backfill. Flooding trench backfill is not recommended. Heavy equipment should not be operated over any pipe until it has been properly backfilled with a minimum of 2 to 3 feet of cover. The utility trench should be systematically backfilled to allow maximum time for natural settlement. Backfill should not occur over porous, wet, or spongy subgrade surfaces. Should these conditions exist, the areas should be removed, replaced and recompacted.

10.0 BORE & JACK RECOMMENDATIONS

Based on the results of our subsurface exploration, it is our opinion that the proposed trenchless (bore-and-jack) operations are feasible and that sufficient ground cover exists to provide stable conditions adjacent to the 60 Freeway for the proposed Tract No. 31556 offsite sewer freeway undercrossing, provided such operations are adequately performed by a qualified contractor(s) who is experienced in bore-and-jack pipe installation methods in the local area. Geotechnical data, obtained from our subsurface exploration, indicates that potential settlement and heave problems are not likely at or adjacent to the proposed bore-and-jack locations, assuming adequate procedures are performed.

It is the contractor's responsibility to design and select the appropriate tunnel construction method, support system and to follow the requirements of the health and safety rules of the State of California pertaining to bore-and-jack/tunnel construction and permit requirements of local agencies such as the City of Moreno Valley or County of Riverside. The contractor should develop an appropriate mitigation plan for deficient soil conditions, as well as a contingency plan for potential emergency conditions, such as loss of ground, excessive settlement and other construction problems. Provisions for controlling running sand and groundwater at localized areas should be provided during the boring operation to reduce the potential for ground loss and ground subsidence. The following geotechnical recommendations are provided for bore-and-jack operations at the offsite sewer alignment location undercrossing, based on our subsurface exploration.

10.1 Utilities and Subsurface Obstructions

The EEI exploratory borings completed during the Supplemental Geotechnical Evaluation (borings B-16 and B-17) were both advanced to a depth of approximately 21.5 feet below the existing ground surface with boring B-16 located immediately north of the 60 Freeway at the proposed "boring" pit location and boring B-17 being located immediately south of the 60 Freeway at the proposed "receiving" pit location. Artificial fill soils were encountered from the surface to depths of 11 feet and 16 feet below existing grade, respectively. The artificial fill soils were generally composed of loose to medium dense, damp to moist, fine to coarse silty sand and sandy silt. The artificial fill soils were underlain by generally medium dense, moist, fine to medium silty sand.

It is possible that underground utilities and other subsurface obstructions will be encountered within the proposed bore-and-jack location undercrossing the 60 Freeway right-of-way, but not likely. However, we recommend that the contractor perform a comprehensive evaluation of the locations of buried utilities and other structures within the proposed bore-and-jack location. Such an evaluation can include, but is not necessarily limited to, advancing a series of potholes and using geophysical methods to help identify the locations of the utilities/structures. It should be understood that if utilities are present within the proposed pipeline alignment, the nature of the utilities' backfill materials might differ from the materials encountered during our subsurface exploration.

10.2 Tunnelman's Ground Classification

Attempts to classify soil characteristics for tunneling operations include the Rock Quality Designation (RQD) by Deere, Rock Mass Rating (RMR) by Bieniawski, Rock Tunneling Quality Index (Q) by Barton, and Tunnelman's Ground Classification by Terzaghi. The RQD, RMR, and Q designations characterize rock masses while the Tunnelman's Ground Classification was derived to describe soil conditions for tunneling through soft sediments. The Tunnelman's Ground Classification **(Table 4)** categorizes predictive soil behaviors for saturated and unsaturated conditions.

Based on the geotechnical conditions observed during our subsurface exploration, we consider the encountered portions of the artificial fill and alluvial soils are comprised of loose to medium dense running soils.

10.3 Jacking and Receiving Pits

Bore-and-jack operations involve the initial construction of a jacking/tunneling pit and a receiving pit at each end of the pipe segment to be jacked. The jacking and receiving pits should be shored as required. The shoring system should be designed as recommended below. The jacking equipment should not impose a reaction of more than 4,000 psf on the soils within the jacking pit. Pipes for use with microtunnelling systems must be designed to withstand the high axial jacking forces, and this is likely to be a far more significant design parameter than any post installation loading. Jacking operations and tunneling operations should be performed in accordance with the Standard Specifications for Public Works Construction, Sections 306-2 and 306-3 of the latest edition. Grouting through the pipe casing after jacking is recommended to fill any possible voids created by the jacking operation.

TABLE 4
TUNNELMAN'S GROUND CLASSIFICATION FOR SOIL

GROUND CLASSIFICATIONS	GROUND BEHAVIOR	TYPICAL SOIL TYPES
Hard	Tunnel heading may be advanced without roof support.	Cemented sand and gravel and over consolidated clay above the groundwater table.
Firm	Ground in which a roof section of a tunnel can be left unsupported for several days without inducing a perceptible movement of the ground.	Loess above the water table, hard clay, marl, cemented sand and gravel when not highly overstressed.
Raveling	Chunks or flakes of soil begin to drop out of roof at some point during the ground-movement period.	Residual soils or soils with clay binder may be fast raveling below the groundwater table and slow raveling above the groundwater table. Stiff fissured clays may be slow raveling or fast raveling depending on the degree of overstress.

TABLE 4
TUNNELMAN'S GROUND CLASSIFICATION FOR SOIL

GROUND CLASSIFICATIONS	GROUND BEHAVIOR	TYPICAL SOIL TYPES
Slow Raveling	The time required to excavate 5-feet of tunnel and install a rib set and lagging in a small tunnel is about 6-hours. Therefore, if the stand-up time of raveling ground is more than 6-hours, using ribs and lagging, such a soil would be classed as slow raveling.	
Fast Raveling	If the stand-up time is less than 6-hours, using ribs and lagging, such a soil would be classed as fast raveling.	
Squeezing	Ground slowly advances into tunnel without any signs of fracturing. The loss of ground caused by squeeze and the resulting settlement of the ground surface can be substantial	Ground with low frictional strength. Rate of squeeze depends on degree of overstress. Stiff to hard clay under high cover may move in combination of raveling at execution surface and squeezing at depths.
Swelling	Ground slowly advances into the tunnel partly or chiefly because of an increase in the volume of the ground. The volume increase is in response to an increase of water content. In every other respect, swelling ground in a tunnel behaves like a stiff non-squeezing, or slowly squeezing, non-swelling clay.	Highly preconsolidated clay with plasticity index greater than about 30, generally containing significant percentages of montmorillonite clay
Running	The removal of lateral support on any surface rising at an angle more than 34° (to the horizontal) is immediately followed by a running movement of the soil particles.	Clean, dry granular materials.
Cohesive Running	If the running ground has a trace of cohesion, then the run is preceded by a brief period of progressive raveling.	Apparent cohesion in moist sand or weak cementation in any granular soil may allow the material to stand for a brief period of raveling before it breaks down and runs. Such behavior is cohesive running.
Very Soft Squeezing	Ground advances rapidly into tunnel in a plastic flow.	
Flowing	Ground supporting a tunnel cannot be classified as flowing ground unless water flows or seeps through it toward the tunnel. For this reason, a flowing condition is encountered only in free air tunnels below the water table or under compressed air when the pressure is not high enough in the tunnel to dry the bottom.	Only occurs in inorganic silt, fine silty sand, clean sand or gravel, or sand-and-gravel with some clay binder. Organic silt may behave either as a flowing or as a very soft, squeezing ground.

10.4 Shoring

The vertical face of the jacking pit and receiving pit may be shored with sheet piles and/or soldier piles and lagging. The face of the shaft also can be supported by ribs and lagging. The details of sheet piling, soldier beam and lagging system may be designed according to the recommendations provided in the following sections of this report. Frequent contact grouting may be necessary to backpack the support during construction to reduce the potential for settlement. While groundwater was not encountered during our subsurface exploration, the shoring contractor should also consider the possibility of localized perched groundwater in the design and installation procedures of the shoring system.

10.5 Lateral Earth Pressures

The shoring system should be designed to resist the pressure exerted by the retained soils and any additional lateral forces due to loads applied near the top of the excavations. A cantilevered shoring system should be designed for an equivalent fluid weight of 35 pcf. Braced shoring walls supporting a level ground surface should be designed for a uniform lateral pressure of 20H psf, where H is the height of the retained earth in feet.

For surcharge loads due to traffic, the shoring should be designed for an additional uniform horizontal pressure of 75 psf for passenger car traffic and 150 psf for heavy truck traffic. For other surcharge loads, the wall should be designed for a uniform horizontal pressure equal to one-third the anticipated surcharge pressure. These parameters all assume a level ground surface and that temporary shoring will not be subject to hydrostatic pressures. The shoring system should be properly embedded beneath the toe of the excavation to provide adequate structural stability.

10.6 Passive Resistance

It is recommended that the design of the shoring system incorporates a passive equivalent fluid weight of 350 pcf for the shoring embedded within relatively competent older alluvium. If utilized, soldier piles should be spaced no closer than 3 diameters on center. The soldier piles should be drilled and backfilled with concrete to the full depth of the passive resistance zone. The area providing the passive resistance can be assumed to have a width equal to twice the concrete pile diameter. The recommended passive pressure for the shoring assumes a horizontal surface for the soil mass extending at least 10 feet in front of the face of the shoring, or three times the height of the surface generating passive pressure, whichever is greater. The shoring system should be embedded a sufficient depth beneath the toe of the excavation to provide structural stability. We recommend that a factor of safety of at least 1.2 be applied to the calculated embedment depth and that the passive pressure be limited to 2,500 psf. The assumed geotechnical conditions should be verified as necessary during shoring construction by a representative of this firm.

10.7 Lagging

If soldier piles are used as shoring, timber lagging may be used between the soldier piles to help support the exposed soils. If lagging is to remain after construction, treated lumber should be used. Lagging should be designed for the full lateral pressure recommended on the previous page. Voids between the soil and lagging should be grouted or slurried to reduce the potential for the voids to propagate to the surface.

10.8 Utility Backfill

Fill around the pipe should be placed in accordance with details shown on the drawings, and should be placed in layers not to exceed 8 inches loose (unless otherwise approved by the geotechnical engineer) and compacted to at least 90 percent of the maximum dry density as determined in accordance with ASTM D 1557 (Modified Proctor). The geotechnical engineer should approve all backfill material. Select material should be used when called for on the drawings, or when required by the geotechnical engineer. Care should be taken during backfill and compaction operations to maintain alignment and prevent damage to the joints. The backfill should be kept free from stones, chunks of highly plastic clay, or other objectionable material. Backfill soils should be non-expansive, non-corrosive, and compatible with native earth materials. Backfill materials and testing should be in accordance with the 2013 CBC, and/or the City of Moreno Valley specifications.

All pipe backfill areas should be graded and maintained in such a condition that erosion or saturation will not damage the pipe bed or backfill. Flooding trench backfill is not recommended. Heavy equipment should not be operated over any pipe until it has been properly backfilled with a minimum two to three feet of cover. The utility trench should be systematically backfilled to allow maximum time for natural settlement. Backfill should not occur over porous, wet, or spongy subgrade surfaces. Should these conditions exist, the areas should be removed, replaced, and recompacted.

10.9 Pre-Construction Survey and Monitoring

Consideration should be given to performing a pre-condition survey of improvements in the area prior to construction, to document any current existing distress. Settlement points should be considered to monitor any settlement of adjacent facilities during construction.

10.10 Other Design Considerations

Excavation, shoring and dewatering systems should be properly designed and installed to minimize the effects of aerial settlement, during construction. The preparation of plans for the excavations, shoring, sheeting, and dewatering systems is normally the responsibility of the contractor. Consideration should be given to characterize the material as the bore-and-jack operations proceed; and based on the behavior of the soil; the support system and method of trenchless construction may be altered accordingly.

10.11 Plan Review

It is recommended that EEI be provided the opportunity to review the final project plans prior to construction. The purpose of this review is to assess the general compliance of the plans with the recommendations provided in this report and the incorporation of these recommendations into the project plans and specifications.

10.12 Observation and Testing During Construction

It is recommended that EEI be retained to observe the bore-and-jack operations as they progress; provide observation and testing services during placement and backfill of underground utilities, observe drilling of soldier piles (if warranted), and to observe final site drainage. This is to observe compliance with the design concepts, specifications and recommendations, and to allow for possible changes in the event that subsurface conditions differ from those anticipated prior to the start of construction

11.0 PLAN REVIEW

Once detailed site and grading plans are available, they should be submitted to this office for review and comment, to reduce the potential for discrepancies between plans and the preliminary recommendations presented herein. If conditions are found to differ substantially from those stated, appropriate recommendations would be provided. Additional field studies may be warranted.

12.0 LIMITATIONS

This Supplemental Geotechnical Evaluation has been conducted in accordance with generally accepted geotechnical engineering principles and practices. Findings provided herein have been derived in accordance with current standards of practice, and no warranty is expressed or implied. Standards of practice are subject to change with time. This Supplemental Geotechnical Evaluation report has been prepared for the sole use of Anderson Consulting Engineers, Inc. (Client), within a reasonable time from its authorization. Site conditions, land use (both onsite and offsite), or other factors may change as a result of man-made influences, and additional work may be required with the passage of time.

This Supplemental Geotechnical Evaluation should not be relied upon by other parties without the express written consent of EEI and the Client; therefore, any use or reliance upon this geotechnical evaluation by a party other than the Client should be solely at the risk of such third party and without legal recourse against EEI, its employees, officers, or directors, regardless of whether the action in which recovery of damages is brought or based upon contract, tort, statue, or otherwise.

The Client has the responsibility to see that all parties to the project, including the designer, contractor, subcontractor, and building official, etc. are aware of this report in its complete form. This report contains information that may be used in the preparation of contract specifications; however, the report is not designed as a specification document, and may not contain sufficient information for use without additional assessment. EEI assumes no responsibility or liability for work or testing performed by others. In addition, this report may be subject to review by the controlling authorities.

APPENDIX C
EARTHWORK AND GRADING GUIDELINES

Geotechnical & Environmental Solutions

EARTHWORK AND GRADING GUIDELINES

GENERAL

These guidelines present general procedures and recommendations for earthwork and grading as required on the approved grading plans, including preparation of areas to be filled, placement of fill and installation of subdrains and excavations. The recommendations contained in the geotechnical report are applicable to each specific project, are part of the earthwork and grading guidelines and would supersede the provisions contained hereafter in the case of conflict. Observations and/or testing performed by the consultant during the course of grading may result in revised recommendations which could supersede these guidelines or the recommendations contained in the geotechnical report. Figures A through O are provided at the back of this appendix, exhibiting generalized cross sections relating to these guidelines.

The contractor is responsible for the satisfactory completion of all earthworks in accordance with provisions of the project plans and specifications. The project soil engineer and engineering geologist (geotechnical consultant) or their representatives should provide observation and testing services, and geotechnical consultation throughout the duration of the project.

EARTHWORK OBSERVATIONS AND TESTING

Geotechnical Consultant

Prior to the commencement of grading, a qualified geotechnical consultant (a soil engineer and engineering geologist) should be employed for the purpose of observing earthwork procedures and testing the fills for conformance with the recommendations of the geotechnical report, the approved grading plans, and applicable grading codes and ordinances.

The geotechnical consultant should provide testing and observation so that determination may be made that the work is being completed as specified. It is the responsibility of the contractor to assist the consultant and keep them aware of work schedules and predicted changes, so that the consultant may schedule their personnel accordingly.

All removals, prepared ground to receive fill, key excavations, and subdrains should be observed and documented by the project engineering geologist and/or soil engineer prior to placing any fill. It is the contractor's responsibility to notify the engineering geologist and soil engineer when such areas are ready for observation.

2195 Faraday Avenue • Suite K • Carlsbad, California 92008-7207 • Ph: 760-431-3747 • Fax: 760-431-3748 • www.eeitiger.com

Laboratory and Field Tests

Maximum dry density tests to determine the degree of compaction should be performed in accordance with American Standard Testing Materials test method ASTM designation D-1557-78. Random field compaction tests should be performed in accordance with test method ASTM designations D-1556-82, D-2937 or D-2922 & D-3017, at intervals of approximately two (2) feet of fill height per 10,000 sq. ft. or every one thousand cubic yards of fill placed. These criteria would vary depending on the soil conditions and the size of the project. The location and frequency of testing would be at the discretion of the geotechnical consultant

Contractor's Responsibility

All clearing, site preparation, and earthwork performed on the project should be conducted by the contractor, with observation by geotechnical consultants and staged approval by the appropriate governing agencies. It is the contractor's responsibility to prepare the ground surface to receive the fill to the satisfaction of the soil engineer, and to place, spread, moisture condition, mix and compact the fill in accordance with the recommendations of the soil engineer. The contractor should also remove all major deleterious material considered unsatisfactory by the soil engineer.

It is the sole responsibility of the contractor to provide adequate equipment and methods to accomplish the earthwork in accordance with applicable grading guidelines, codes or agency ordinances, and approved grading plans. Sufficient watering apparatus and compaction equipment should be provided by the contractor with due consideration for the fill material, rate of placement, and climatic conditions. If, in the opinion of the geotechnical consultant, unsatisfactory conditions such as questionable weather, excessive oversized rock, deleterious material or insufficient support equipment are resulting in a quality of work that is not acceptable, the consultant will inform the contractor, and the contractor is expected to rectify the conditions, and if necessary, stop work until conditions are satisfactory.

The contractor will properly grade all surfaces to maintain good drainage and prevent ponding of water. The contractor will take action to control surface water and to prevent erosion control measures that have been installed.

SITE PREPARATION

All vegetation including brush, trees, thick grasses, organic debris, and other deleterious material should be removed and disposed of offsite, and must be concluded prior to placing fill. Existing fill, soil, alluvium, colluvium, or rock materials determined by the soil engineer or engineering geologist as unsuitable for structural in-place support should be removed prior to fill placement. Depending upon the soil conditions, these materials may be reused as compacted fills. Any materials incorporated as part of the compacted fills should be approved by the soil engineer.

Any underground structures such as cesspools, cisterns, mining shafts, tunnels, septic tanks, wells, pipelines, or other structures not located prior to grading are to be removed or treated in a manner recommended by the soil engineer. Soft, dry, spongy, highly fractured, or otherwise unsuitable ground extending to such a depth that surface processing cannot adequately improve the condition should be over excavated down to firm ground and approved by the soil engineer before compaction and filling operations continue. Over excavated and processed soils which have been properly mixed and moisture-conditioned should be recompacted to the minimum relative compaction as specified in these guidelines.

Existing ground which is determined to be satisfactory for support of the fills should be scarified to a minimum depth of six (6) inches, or as directed by the soil engineer. After the scarified ground is brought to optimum moisture (or greater) and mixed, the materials should be compacted as specified herein. If the scarified zone is greater than 6 inches in depth, it may be necessary to remove the excess and place the material in lifts restricted to six (6) inches in compacted thickness.

Existing grind which is not satisfactory to support compacted fill should be over excavated as required in the geotechnical report or by the onsite soils engineer and/or engineering geologists. Scarification, discing, or other acceptable form of mixing should continue until the soils are broken down and free of large fragments or clods, until the working surface is reasonably uniform and free from ruts, hollows, hummocks, or other uneven features which would inhibit compaction as described above.

Where fills are to be placed on ground with slopes steeper than 5:1 (horizontal to vertical) gradient, the ground should be benched. The lowest bench, which will act as a key, should be a minimum of 12 feet wide and should be at least two (2) feet deep into competent material, approved by the soil engineer and/or engineering geologist. In fill over cut slope conditions, the recommended minimum width of the lowest bench or key is at least 15 feet with the key excavated on competent material, as designated by the Geotechnical Consultant. As a general rule, unless superseded by the Soil Engineer, the minimum width of fill keys should be approximately equal to one-half (½) the height of the slope.

Standard benching is typically four feet (minimum) vertically, exposing competent material. Benching may be used to remove unsuitable materials, although it is understood that the vertical height of the bench may exceed four feet. Pre stripping may be considered for removal of unsuitable materials in excess of four feet in thickness.

All areas to receive fill, including processed areas, removal areas, and toe of fill benches should be observed and approved by the soil engineer and/or engineering geologist prior to placement of fill. Fills may then be properly placed and compacted until design grades are attained.

COMPACTED FILLS

Earth materials imported or excavated on the property may be utilized as fill provided that each soil type has been accepted by the soil engineer. These materials should be free of roots, tree branches, other organic matter or other deleterious materials. All unsuitable materials should be removed from the fill as directed by the soil engineer. Soils of poor gradation, undesirable expansion potential, or substandard strength characteristics may be designated unsuitable by the consultant and may require mixing with other earth materials to serve as a satisfactory fill material.

Fill materials generated from benching operations should be dispersed throughout the fill area. Benching operations should not result in the benched material being placed only within a single equipment width away from the fill/bedrock contact.

Earthwork and Grading Guidelines

Oversized materials, defined as rock or other irreducible materials with a maximum size exceeding 12 inches in one dimension, should not be buried or placed in fills unless the location of materials and disposal methods are specifically approved by the soil engineer. Oversized material should be taken offsite or placed in accordance with recommendations of the soil engineer in areas designated as suitable for rock disposal. Oversized material should not be placed vertically within 10 feet of finish grade or horizontally within 20 feet of slope faces.

To facilitate trenching, rock should not be placed within the range of foundation excavations or future utilities unless specifically approved by the soil engineer and/or the representative developers.

If import fill material is required for grading, representative samples of the material should be analyzed in the laboratory by the soil engineer to determine its physical properties. If any material other than that previously analyzed is imported to the fill or encountered during grading, analysis of this material should be conducted by the soil engineer as soon as practical.

Fill material should be placed in areas prepared to receive fill in near-horizontal layers that should not exceed six (6) inches compacted in thickness. The soil engineer may approve thicker lifts if testing indicates the grading procedures are such that adequate compaction is being achieved. Each layer should be spread evenly and mixed to attain uniformity of material and moisture suitable for compaction.

Fill materials at moisture content less than optimum should be watered and mixed, and "wet" fill materials should be aerated by scarification, or should be mixed with drier material. Moisture conditioning and mixing of fill materials should continue until the fill materials have uniform moisture content at or above optimum moisture.

After each layer has been evenly spread, moisture-conditioned and mixed, it should be uniformly compacted to a minimum of 90 percent of maximum density as determined by ASTM test designation, D 1557-78, or as otherwise recommended by the soil engineer. Compaction equipment should be adequately sized and should be reliable to efficiently achieve the required degree of compaction.

Where tests indicate that the density of any layer of fill, or portion thereof, is below the required relative compaction or improper moisture content, the particular layer or portion will be reworked until the required density and/or moisture content has been attained. No additional fill will be placed in an area until the last placed lift of fill has been tested and found to meet the density and moisture requirements, and is approved by the soil engineer.

Compaction of slopes should be accomplished by over-building the outside edge a minimum of three (3) feet horizontally, and subsequently trimming back to the finish design slope configuration. Testing will be performed as the fill is horizontally placed to evaluate compaction as the fill core is being developed. Special efforts may be necessary to attain the specified compaction in the fill slope zone. Final slope shaping should be performed by trimming and removing loose materials with appropriate equipment. A final determination of fill slope compaction should be based on observation and/or testing of the finished slope face.

If an alternative to over-building and cutting back the compacted fill slope is selected, then additional efforts should be made to achieve the required compaction in the outer 10 feet of each lift of fill by undertaking the following:

- Equipment consisting of a heavy short-shanked sheepsfoot should be used to roll (horizontal) parallel to the slopes continuously as fill is placed. The sheepsfoot roller should also be used to roll perpendicular to the slopes, and extend out over the slope to provide adequate compaction to the face slope.

- Loose fill should not be spilled out over the face of the slope as each lift is compacted. Any loose fill spilled over a previously completed slope face should be trimmed off or be subject to re-rolling.

- Field compaction tests will be made in the outer two (2) to five (5) feet of the slope at two (2) to three (3) foot vertical intervals, subsequent to compaction operations.

- After completion of the slope, the slope face should be shaped with a small dozer and then re-rolled with a sheepsfoot to achieve compaction to near the slope face. Subsequent to testing to verify compaction, the slopes should be grid-rolled to achieve adequate compaction to the slope face. Final testing should be used to confirm compaction after grid rolling.

- Where testing indicates less than adequate compaction, the contractor will be responsible to process, moisture condition, mix and recompact the slope materials as necessary to achieve compaction. Additional testing should be performed to verify compaction.

- Erosion control and drainage devices should be designed by the project civil engineer in compliance with the ordinances of the controlling governmental agencies, and/or in accordance with the recommendations of the soil engineer or engineering geologist.

EXCAVATIONS

Excavations and cut slopes should be observed and mapped during grading by the engineering geologist. If directed by the engineering geologist, further excavations or over-excavation and refilling of cut areas should be performed. When fills over cut slopes are to be graded, the cut portion of the slope should be observed by the engineering geologist prior to placement of the overlying fill portion of the slope. The engineering geologist should observe all cut slopes and should be notified by the contractor when cut slopes are started.

If, during the course of grading, unanticipated adverse or potentially adverse geologic conditions are encountered, the engineering geologist and soil engineer should investigate, evaluate and make recommendations to mitigate (or limit) these conditions. The need for cut slope buttressing or stabilizing should be based on as-grading evaluations by the engineering geologist, whether anticipated previously or not.

Unless otherwise specified in soil and geological reports, no cut slopes should be excavated higher or steeper than that allowed by the ordinances of controlling governmental agencies. Additionally, short-term stability of temporary cut slopes is the contractor's responsibility.

Erosion control and drainage devices should be designed by the project civil engineer and should be constructed in compliance with the ordinances of the controlling governmental agencies, and/or in accordance with the recommendations of the soil engineer or engineering geologist.

SUBDRAIN INSTALLATION

Subdrains should be installed in accordance with the approved embedment material, alignment and details indicated by the geotechnical consultant. Subdrain locations or construction materials should not be changed or modified without approval of the geotechnical consultant. The soil engineer and/or engineering geologist may recommend and direct changes in subdrain line, grade and drain material in the field, pending exposed conditions. The location of constructed subdrains should be recorded by the project civil engineer.

COMPLETION

Consultation, observation and testing by the geotechnical consultant should be completed during grading operations in order to state an opinion that all cut and filled areas are graded in accordance with the approved project specifications.

After completion of grading and after the soil engineer and engineering geologist have finished their observations, final reports should be submitted subject to review by the controlling governmental agencies. No additional grading should be undertaken without prior notification of the soil engineer and/or engineering geologist.

All finished cut and fill slopes should be protected from erosion, including but not limited to planting in accordance with the plan design specifications and/or as recommended by a landscape architect. Such protection and/or planning should be undertaken as soon as possible after completion of grading.

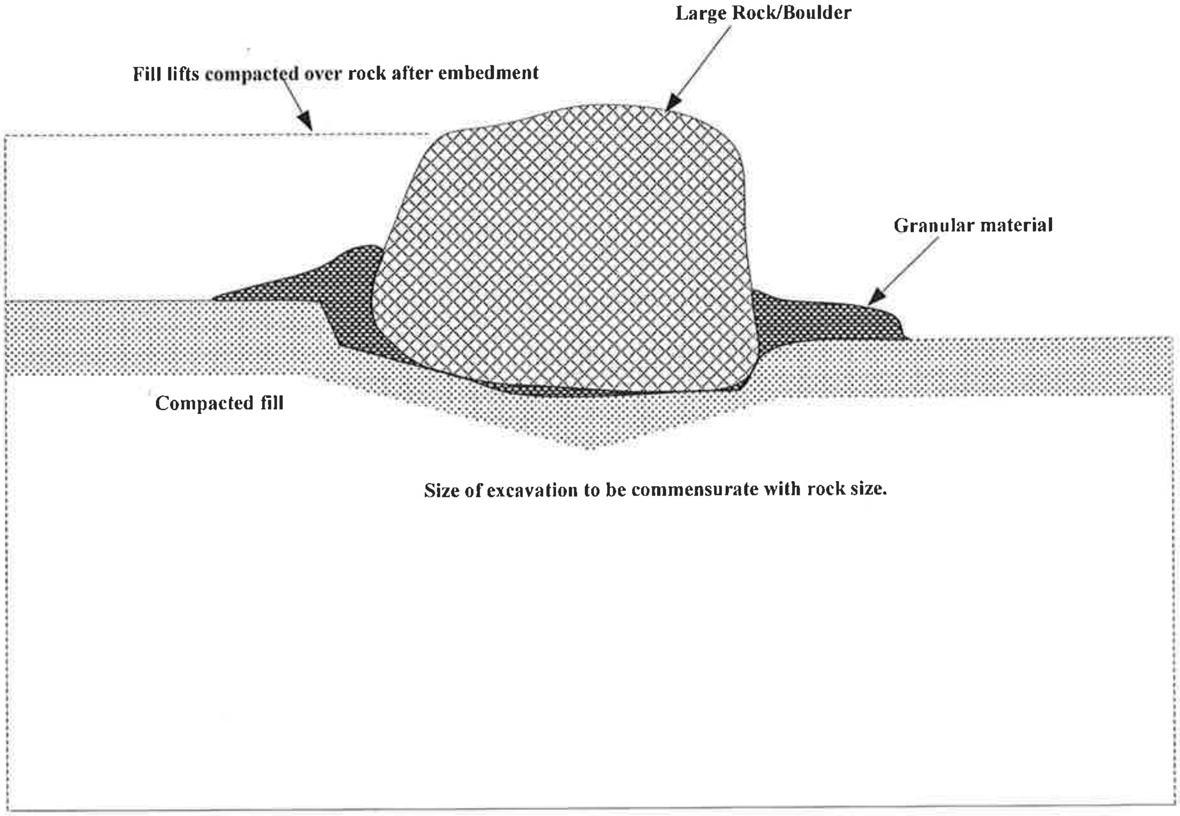
ROCK DISPOSAL PITS



Note:
(1) Large rock is defined as having a diameter larger than 3 feet in maximum size.
(2) Pit shall be excavated into compacted fill to a depth equal to half of the rock size.
(3) Granular soil shall be pushed into the pit and then flooded around the rock using a sheepsfoot to help with compaction.
(4) A minimum of 3 feet of compacted fill should be laid over each pit.
(5) Pits shall have at least 15 feet of separation between one another, horizontally.
(6) Pits shall be placed at least 20 feet from any fill slope.
(7) Pits shall be used only in deep fill areas.

Re: Fire Department Response to Request for Information Regarding Fire Protection and Emergency Medical Services for the Ironwood Villages Project

Dear Mr. Allee,

My staff and I have carefully reviewed the Ironwood Villages Proposed Project, Tentative Tract Map No. 37001. We have carefully researched and analyzed the information you provided to the City in order to determine what the impacts to the Fire Department will be due to your proposed project. Our responses below contain information from historical data, current records, and industry standards so that we could provide you with as comprehensive of a review as possible based on the initial data you have provided to the City.

1. **Service Area and Facilities.** The Moreno Valley Fire Department has a service area of 51.5 square miles and a population estimate of 197,695 (2011). Our facilities and daily staffing consist of:

Station Number	***Station Address***	***Daily Personnel***	***Equipment***
Station 2 (Sunnymead)	24935 Hemlock Ave.	7 Firefighters	1 engine 1 aerial ladder truck 1 urban search & rescue trailer 1 rescue Squad
Station 6 (Towngate)	22250 Eucalyptus Ave.	3 Firefighters	1 engine 1 reserve aerial ladder truck 1 reserve engine
Station 48 (Sunnymead Ranch)	10511 Village Rd.	3 Firefighters	1 engine
Station 58 (Moreno Beach)	28040 Eucalyptus Ave.	3 Firefighters	1 engine 1 rescue squad
Station 65 (Kennedy Park)	15111 Indian St.	3 Firefighters	1 engine 1 reserve engine
Station 91 (College Park)	16110 Lasselle St.	7 Firefighters	1 engine 1 rescue squad

Station 99 (Morrison Park)	13400 Morrison St.	3 Firefighters 1 Battalion Chief	1 Engine 1 Staff Vehicle

2. **Standard Response.** A Standard Response is defined as the minimum amount of staffing and equipment that must reach a specific emergency response location within a maximum prescribed travel time. Standard response coverage consists of three key elements:
    a. Distribution – Station and resource locations needed to ensure rapid response. Per the National Fire Protection Association (NFPA) 1710 standard and the Moreno Valley Fire Department Strategic Plan 2012-2022, an engine company is to arrive on scene within four minutes of travel time to fire incidents and emergency medical aid calls 90% of the time.
    b. Concentration – Spacing of multiple resources arranged so that an initial effective response force can arrive on scene within sufficient time frames. Per NFPA 1710 and the Moreno Valley Fire Department Strategic Plan 2012-2022, a complete first alarm fire assignment is to arrive on scene within eight minutes of travel time 90% of the time.
    c. Staffing levels – number of personnel and their task assignment. This consists of four person truck companies and three person engine companies.
    d. The standard amount of equipment dispatched to emergency calls for service is listed in the table below:

Incident Type	**Engine**	**Truck**
Medical	Minimum of 1 engine or 1 truck, whichever is closest.	
Vehicle Fire	2	0
Residential Structure Fire	3	1
Commercial Structure Fire	4	1
Hazardous Materials Incident	1 Engine, 1 Hazardous Materials Unit, 1 Hazardous Materials Squad, 1 Battalion Chief, and Environmental Health.	
Traffic Accident	Minimum of 1 engine or 1 truck, whichever is closest. Could be 2 engines and 1 truck depending on the nature of the incident	

    e. As part of CAL Fire / Riverside County Fire, the typical first alarm fire response to a commercial structure fire will consist of four Type 1 fire engines, one aerial ladder truck, and one Chief Officer. While Fire Station 58, 99, 2, and 91 are the closest fire stations (respectfully) to the proposed Ironwood Villages Project, it cannot be confirmed that an initial response would in fact include resources from those facilities due to the possibility that the equipment may be committed to other emergency calls for services. However, the City of Moreno Valley Fire Department does participate in the Regionalized Cooperative Fire Protection Delivery System of CAL Fire / Riverside County Fire. This system provides assurances that the closest and most appropriate resources are dispatched to all requests for Fire Department emergency services regardless of jurisdiction.

f. Fire Station 58 is the closest fire station to the proposed Ironwood Villages Project. The approximate distance from Fire Station 58 to the middle of the project area utilizing existing roads is 2.0 miles. This equates to an estimated travel time of 5 minutes for the first arriving engine for any emergency incidents and a 6 minute response time for the first arriving aerial ladder truck company. A full first alarm fire response to a commercial fire occurring within the proposed Ironwood Villages Project would minimally take 11 minutes 45 seconds, exceeding the NFPA 1710 standard.

g. The current Insurance Services Offices (ISO) Rating of the City Moreno Valley Fire Department is Class 4.

3. **Fire Risk.** Risk assessment involves analyzing threats or hazards facing a community. This includes: 1) performing a hazard assessment which examines building type, density of structures, occupant loading, and life safety; 2) performing a vulnerability assessment which evaluates the negative economic valuation and impact on the community; and 3) conducting a capacity assessment which analyzes the resources available to mitigate hazards, both from a pre-planning perspective and fire suppression ability. The buildings being proposed for the Ironwood Villages project are considered to be in both the high fire risk category and non-fire high hazard risk category.

4. **Risk for emergency incidents during construction.** Emergency incidents during construction are considered to be low frequency, high-risk occurrences. The closest existing fire services to the project area, which is Fire Station 58, will be impacted by the occurrence of both fire and non-fire related emergency incidents. The arrival times to the Ironwood Villages project for Moreno Valley Fire Department units from existing Moreno Valley Fire station locations will be extended since no existing fire station lies within the proposed project area and the project area lies well outside the NFPA 1710 standard of four minutes of travel time for the first engine to arrive on scene of an emergency response and eight minutes of travel time for a full first alarm fire assignment to arrive on scene of a fire emergency.

   a. **Fire Emergencies.** Buildings under construction are susceptible to fire and are more likely to have a high rate of fire spread due to absence of fire protection systems, fire detection systems, and fire protection features. These buildings also lack compartmentalization of the interior to slow the rate of fire spread. Regardless of the types of building materials present, the construction, alteration or demolition operations for a building can cause severe fires to occur which may result in significant dollar loss, injuries, and death. The probability of these incidents occurring can be reduced by the application of adopted fire codes and safe work practices. Additionally, the extent of fire damage can be limited with proper fire protection management, pre-fire planning and reasonable fire protection requirements.

b. **Non Fire Emergencies.** Non-fire related emergencies will occur during construction within a project area. These emergencies include hazardous materials incidents, confined space rescues, falls from significant heights, transportation related accidents and exposure related incidents. Mitigation of these types of accidents typically occurs through following CAL OSHA requirements with the exception of transportation related accidents.

5. **Equipment.** Fire Station 58 will remain the closest fire station to the proposed Ironwood Villages Project for responding to emergency calls for service. An aerial ladder truck in Moreno Valley will remain stationed at Fire Station 2 and provides aerial capabilities within eight minutes of travel time.

   The proposed Ironwood Villages project when fully constructed will benefit from existing fire protection located in the City of Moreno Valley. Also, fire protection serving the proposed project is consistent with NFPA 1710 recommended response time of four minutes of travel time for a first arriving fire engine as well as having a full first alarm fire assignment on scene within eight minutes of travel time. As such, the Fire Department would be able to mitigate an emergency requiring the specialized services of either a fire engine or an aerial ladder truck with its current equipment and three closest fire station locations in a timely manner.

6. **Service Levels.** The Moreno Valley Fire Department currently maintains fire services at a level that is sufficient to accommodate municipal demands such as residential, commercial, industrial, and wildland urban interface resource needs. The proposed Ironwood Villages project will not impact this service and service levels will be sufficient without the addition of equipment and/or fire station locations.

7. **Mutual Assistance.** As stated previously, the City of Moreno Valley participates in the Regionalized Cooperative Fire Protection Delivery System of CAL Fire/Riverside County Fire Department. This system provides assurances that the closest and most appropriate resources are dispatched to all requests for Fire Department emergency services regardless of jurisdictional boundaries. The Riverside County Department of Environmental Health has the regulatory authority throughout the County for Hazardous Materials and will provide assistance when requested to do so. The Fire Department anticipates that a project of this magnitude will not significantly increase the number of hazardous materials incidents experienced within the City of Moreno Valley.

8. **Impacts and Mitigation.** The proposed Ironwood Villages project is not expected to significantly increase the calls for services of the Fire Department. The Fire Department operates a fire station within four minutes of travel time to the project area for emergency responses and an aerial ladder truck within eight minutes of travel time for a first alarm fire assignment. As such, this will result in the Fire Department being able to achieve the NFPA 1710 response standard for a residential first alarm fire assignment. This type of assignment requires all first alarm fire apparatus to be on scene within eight minutes of travel time. Utilizing existing fire services will not result in significant impacts to the

public and businesses neither within the project area, nor to the existing citizens and areas of the community that currently exist.

The information provided in this analysis is based on current data obtained from the information submitted to the City for the proposed Ironwood Villages project. The findings in this letter are non-inclusive as other issues may arise during actual plan review. All final recommendations in regards to this project will be based on plan review at the time of plan submittal and current code requirements.

Should you have any questions, or wish to discuss the contents of this report, please feel free to contact me at (951) 486-6780 or by email at abdula@moval.org.

Sincerely,

Abdul R. Ahmad
Fire Chief

Re: Information Requested Regarding School Services for the Ironwood Village Project in the City of Moreno Valley

Dear Mr. Allee:

We hope to be able to answer all your questions for the MND you are preparing for the Ironwood Village Project.

SCHOOLS OF ATTENDANCE:
Currently, the schools that will provide educational services in the area of this project is:

Elementary: Grades TK – 5
Cloverdale Elementary
12050 Kitching St, Moreno Valley, CA 92557

Middle: Grades 6 – 8
Palm Middle
11900 Swanson Avenue, Moreno Valley, CA 92557

High: Grades 9-12
Valley View High School*
13135 Nason Street, Moreno Valley, CA 92557

*New High School: We are in the process of constructing a fifth (5) high school that would serve this area. The land has been purchased and due diligence is being performed. We hope to have this new high school ready for occupancy by 2020, with a capacity of 2,400 students. Initial enrollment will be 9th grade students only; second year 9th and 10th; third year 9-11; and fourth year 9-12.

STUDENT GENERATION RATES sourced from the Fee Justification Report for New Residential & Commercial/Industrial Development dated April 21, 2016:
Elementary: .3019
Middle: .1500
High: .1973

EXISTING PERMANENT AND PORTABLE CLASSROOMS:

Cloverdale:	12 Portables, 22 Permanent Classrooms
Palm:	5 Portables, 51 Permanent Classrooms
Valley view:	27 Portables, 73 Permanent Classrooms

EXISTING ENROLLMENT:
As of CBEDS Day, October 7, 2015, the enrollment including SELPA SDC and Middle College students was:

Cloverdale:	770
Palm:	1,243
Valley View:	2,636

PROJECTED ENROLLMENT 2019/2020:		DESIGN CAPACITY 2019/2020:	
Cloverdale:	800	Cloverdale:	850
Palm:	1300	Palm:	1465
Valley View:	2636	Valley View:	2638

IMPROVEMENTS TO EXISTING SCHOOLS:

Moreno Valley Unified School District has created a 2013/2014 Facilities Master Plan that was adopted by our Board November 12, 2013. This Facilities Master Plan can be found on our District's website, www.mvusd.net.

Within this document, the following improvements have been identified, dependent upon funding availability:

Cloverdale Elementary:
Removal of all 12 portable classrooms and 1 portable restroom building.
The construction of a 2-story permanent classroom building (10 classrooms + restrooms), to replace the 12 classroom portables and 1 portable restroom building.
Add staff toilets to Classroom Building C and D.
21st Century Technology Upgrades

Palm Middle:
Parking Expansion and reconfiguration; separate bus and parent drop off.
Upgrades to the Library and Multipurpose Room.
Replacement of drinking fountains.
Upgrade exterior fencing and gates.
New enclosed gymnasium to replace existing pavilion.
Food Service and Locker Room Transformation.
Classroom Building Transformation including Science classrooms (interior finishes, ceilings and energy efficient lighting).

Valley View High:
Classroom Buildings Transformation including Science and Special Education (SDC Therapy) Classrooms.
New defined and secured point of entry.
Transformation of gymnasium, locker rooms and weight rooms.
Food Service Area Transformation.
New girls' softball field.
New lunch shelter
New Guard Shack at main parking lot entrance.
Removal of portable classrooms after construction of High School No. 5.
New Culinary Arts program.
21st Century Technology Upgrades

We hope this has answered all of your questions. If we can be of further assistance, please do not hesitate to contact us, (951) 571-7690.

Sincerely,

Sergio San Martin
Director
Facilities Planning and Development
MORENO VALLEY USD

/cla

1. Police station(s) and/or other facilities providing police services to the Project site;
   - The city of Moreno Valley contracts their police service with the Riverside County Sheriff's Department.

2. Please provide information regarding police station(s) serving the Project site, including:
   - The Moreno Valley Police Station is located at 22850 Calle San Juan de Los Lagos, Moreno Valley 92552. The station phone number is 951-486-6700 and the non-emergency crime reporting phone number is 951-247-8700

a. Staffing and equipment for each police facility serving the Project site (i.e., patrol cars, total full-time and part-time staff, number of officers on 24-hour duty):
   - Currently, the Moreno Valley Police Dept. has 199 full time employees. 150 sworn officers and 49 non-sworn (front office staff, support personnel). The number of deputies patrolling during a 24 hour period varies during time of day.

b. Population served and boundaries of police facilities;
   - The population of Moreno Valley is approximately 207,000.

c. Special service teams (i.e., SWAT and K-9) available within the police stations;
   - Because Moreno Valley contracts their police service through the Riverside County Sheriff's Department, they have access to all of the county services; SWAT Team, helicopter, dive team, off highway enforcement team, bomb squad, etc.

d. A general overview of the MVPD's emergency response system (i.e., dispatch system, standard procedures and protocols, etc.);
   - Emergencies are handled on a case by case basis and, if needed, the Moreno Valley Police Dept. can request assistance from surrounding agencies. Moreno Valley Police Dept. also utilizes the Sheriff's Department dispatching system. Dispatch phone number is 951-776-1099

e. Most recent data on associated response times for the station/facility serving the Project area and the overall MVPD, if known;
   - Response times vary depending on the nature of the call. The dispatchers and police department use a priority system. Serious in-progress crimes or crimes that threaten life are priority 1. Priority 1 calls will immediately be handled by any available officer. An example of a priority 2 call would be a residential alarm. Priority 2 calls will be handled once an officer becomes available. Priority 3 and 4 calls are crimes that are not in progress and an officer will respond once all priority 1 and 2 calls have been handled.

f. Crime statistics for police facilities serving the Project site.
   - Crime statistics are available at www.crimereports.com or www.spotcrime.com

3. What is the MVPD's response time goals(s)?
   - The goal is to handle all high priority calls immediately.

4. What would be the anticipated MVPD response time for crime incidents to the Project site with the project? What would be the response time goal to the site with the Project?
   - Response time will depend on the nature and priority of the call.

5. Any planned improvements to the police protection facilities in the service area of the Project site (i.e., expansion, new facilities, additional staffing, etc.)? If so, please describe.

- At this time, there are no planned improvements for the police department facilities.

6. Would Project implementation require the physical expansion of an existing police station(s), a new police station, or additional staffing to the police protection facilities servicing the Project site? If so, please describe.

- This project does not require the Moreno Valley Police Department to expand their existing facility

a. If any new staff required, how many and what position?

- No new staff will be required due to the implementation of this project

b. If any new staff required, could the new staff be accommodated within existing police station(s) without the need for physical expansion of the existing stations(s)? N/A

7. Any other design features or special police protection requirements due to the specific attributes of the project?

Some of the recommendations from the police department for this project would be;

- Address numbers on all buildings/residences should be placed in the most visible location on the building and be illuminated. Address numbers should also be painted on the curb in front of each residence.
- The parking lots, walking trails, street and buildings should be well lit. Minimize the shadows cast by landscaping and trees on the property, walkways and public areas.
- Addition of a city wide camera system at the corner of Nason Street and Ironwood Avenue.
- If there will be one or more community mailbox areas they need to be well lit, in a highly visible public place and designed to resist mail theft.
- The long south main street should have some type of design, like speed bumps, dips or similar objects, to reduce vehicle speed.

Subject: RE: Moreno Valley Public Library Request

Claudia,
Sorry, I didn't remember that you were waiting on anything from me. My information in blue below:

Please provide facility information for each MVPL library serving the Project site, including
a. Size of library buildings (square footage); 15,000 sq. ft.
b. Personnel (paid employees and volunteers); 23 employees, Avg. 32 volunteers per month at avg. 10 hrs. each. (most of these are individuals who come in from other agencies and provide assistance with income tax, Covered California, veteran's services… Gardening classes, art classes…
c. Collection size and amenities; collection size 82,405.
d. Programmed or target service population (please indicate the basis for the population);
I assume this would be the entire MV population
e. Actual population served; Same as above
f. Census tracts that compromise each of the library's service area (if known) and; Entire City

2. Planned, funded, and/or scheduled service improvements, construction or expansions to MVPL facilities that would serve the Project site; N/A

3. Would Project implementation require the physical expansion of an existing library(s) or a new library serving the Project site? If so, please describe. NO

4. Please confirm MVPL's standards and goals used to assess the adequacy of library facilities and potential impacts from Project development. N/A

Rick:

I met with Terrie regarding the Library questions – we went over the Development Impact fees that would go to the Library.
It was my understanding that HR/Library Services were still working on the other questions (employee #s, where a future branch may go, etc) and would send them directly to PCR.

1 INTRODUCTION

This report presents the results of the traffic impact analysis (TIA) for the proposed Ironwood Residential (TTM No. 37001) ("Project"), which is located north of Ironwood Avenue and between Nason Street and Oliver Street, in the City of Moreno Valley as shown on Exhibit 1-1.

The purpose of this traffic impact analysis is to evaluate the potential impacts to traffic and circulation associated with the development of the proposed Project, and recommend improvements to mitigate impacts considered significant in comparison to established regulatory thresholds. As directed by City of Moreno Valley staff, this TIA has been prepared in accordance with the City of Moreno Valley Transportation Engineering Division's *Traffic Impact Analysis Preparation Guide* (August 2007). (1)

1.1 PROJECT OVERVIEW

The Project is proposed to consist of 181 single family detached residential dwelling units. Per the City's traffic study guidelines, the Opening Year will have a five (5) year minimum horizon. As such, the Opening Year analysis will assess 2020 traffic conditions.

Trips generated by the Project's proposed land uses have been estimated based on trip generation rates collected by the Institute of Transportation Engineers (ITE) and presented in ITE's most recent edition of *Trip Generation* (9th Edition, 2012). (2) The Project is anticipated to generate a net total of approximately 1,723 trip-ends per day with 136 AM peak hour trips and 181 PM peak hour trips. The assumptions and methods used to estimate the Project's trip generation characteristics are discussed in detail in Section 4.1 *Project Trip Generation* of this report.

1.2 ANALYSIS SCENARIOS

Consistent with the City of Moreno Valley traffic study guidelines, potential impacts to traffic and circulation will be assessed for each of the following conditions:

- Existing (2015) (1 scenario)
- Existing plus Project (1 scenario)
- Opening Year Cumulative (2020), Without and With Project (2 scenarios)

1.2.1 EXISTING (2015) CONDITIONS

Information for Existing conditions is disclosed to represent the baseline traffic conditions as they existed at the time this report was prepared.

EXHIBIT 1-1: PRELIMINARY TENTATIVE TRACT MAP

1.2.2 Existing Plus Project Conditions

The Existing Plus Project (E+P) analysis determines significant traffic impacts that would occur on the existing roadway system with the addition of Project traffic. The E+P analysis is intended to identify the Project-specific impacts associated solely with the development of the proposed Project based on a comparison of the E+P traffic conditions to Existing conditions.

1.2.3 Opening Year Cumulative (2020) Conditions

To account for background traffic, other known cumulative development projects in the study area were included in addition to 10.41% of ambient growth for Opening Year Cumulative traffic conditions in conjunction with traffic associated with the proposed Project. Although it is unlikely that these cumulative projects would be fully built and occupied by Year 2020, they have been included in an effort to conduct a conservative analysis and overstate and opposed to understate potential cumulative traffic impacts.

The currently adopted Southern California Association of Governments (SCAG) 2012 Regional Transportation Plan (RTP) (April 2012) growth forecasts for the unincorporated areas of the City of Moreno Valley identifies projected growth in population of 187,400 in 2008 to 255,200 in 2035, or a 36.2 percent increase over the 27 year period. (3) The change in population equates to roughly a 1.15 percent growth rate compounded annually. Similarly, growth over the same 27 year period in households is projected to increase by 42.5 percent, or 1.32 percent annual growth rate. Finally, growth in employment over the same 27 year period is projected to increase by 99.4 percent, or a 2.59 percent annual growth rate.

Based on a comparison of Existing traffic volumes to the Horizon Year (2035) forecasts, the average growth rate is estimated at approximately 3.17 percent compounded annually between Existing and Horizon Year (2035) traffic conditions. The annual growth rate at each individual intersection is not lower than 2.08 percent compounded annually to as high as 4.20 percent compounded annually over the same time period. Therefore, the annual growth rate utilized for the purposes of this analysis would appear to conservatively approximate the anticipated regional growth in traffic volumes in the City of Moreno Valley for both Opening Year Cumulative and Horizon Year (2035) traffic conditions, especially when considered along with the addition of project-related traffic. As such, the growth in traffic volumes assumed in this traffic impact analysis would tend to overstate as opposed to understate the potential impacts to traffic and circulation.

1.2.4 Horizon Year (2035) Conditions

The Horizon Year (2035) Without Project traffic conditions were derived from the Riverside County Transportation Analysis Model (RivTAM) modified to represent Horizon Year conditions for the City of Moreno Valley using accepted procedures for model forecast refinement and smoothing. The traffic forecasts reflect the area-wide growth anticipated between Existing conditions and Horizon Year conditions. The Horizon Year With Project traffic forecasts were determined by adding the Project traffic to the Horizon Year Without Project traffic forecasts from the RivTAM model. The Horizon Year traffic forecasts used in the traffic analysis were refined with existing peak hour traffic count data collected at intersection analysis locations. The initial estimate of the future peak hour turning movements has, therefore, been reviewed for reasonableness. The reasonableness checks performed include a review of traffic flow conservation in addition to a comparison with the Existing and Opening Year Cumulative traffic volumes. Where necessary, the Horizon Year volumes have been adjusted to achieve flow conservation, reasonable growth, and reasonable diversion between parallel routes.

The Horizon Year Without and With Project traffic conditions analyses will be utilized to determine if improvements funded through regional transportation mitigation fee programs, such as the TUMF and DIF programs, or other approved funding mechanism can accommodate the long-range cumulative traffic at the target LOS identified in the City of Moreno Valley General Plan. (4) If the "funded" improvements can provide the target LOS, then the Project's payment into TUMF and/or DIF will be considered as long-range cumulative mitigation through the conditions of approval. Other improvements needed beyond the "funded" improvements (such as localized improvements to non-TUMF facilities) are identified as such.

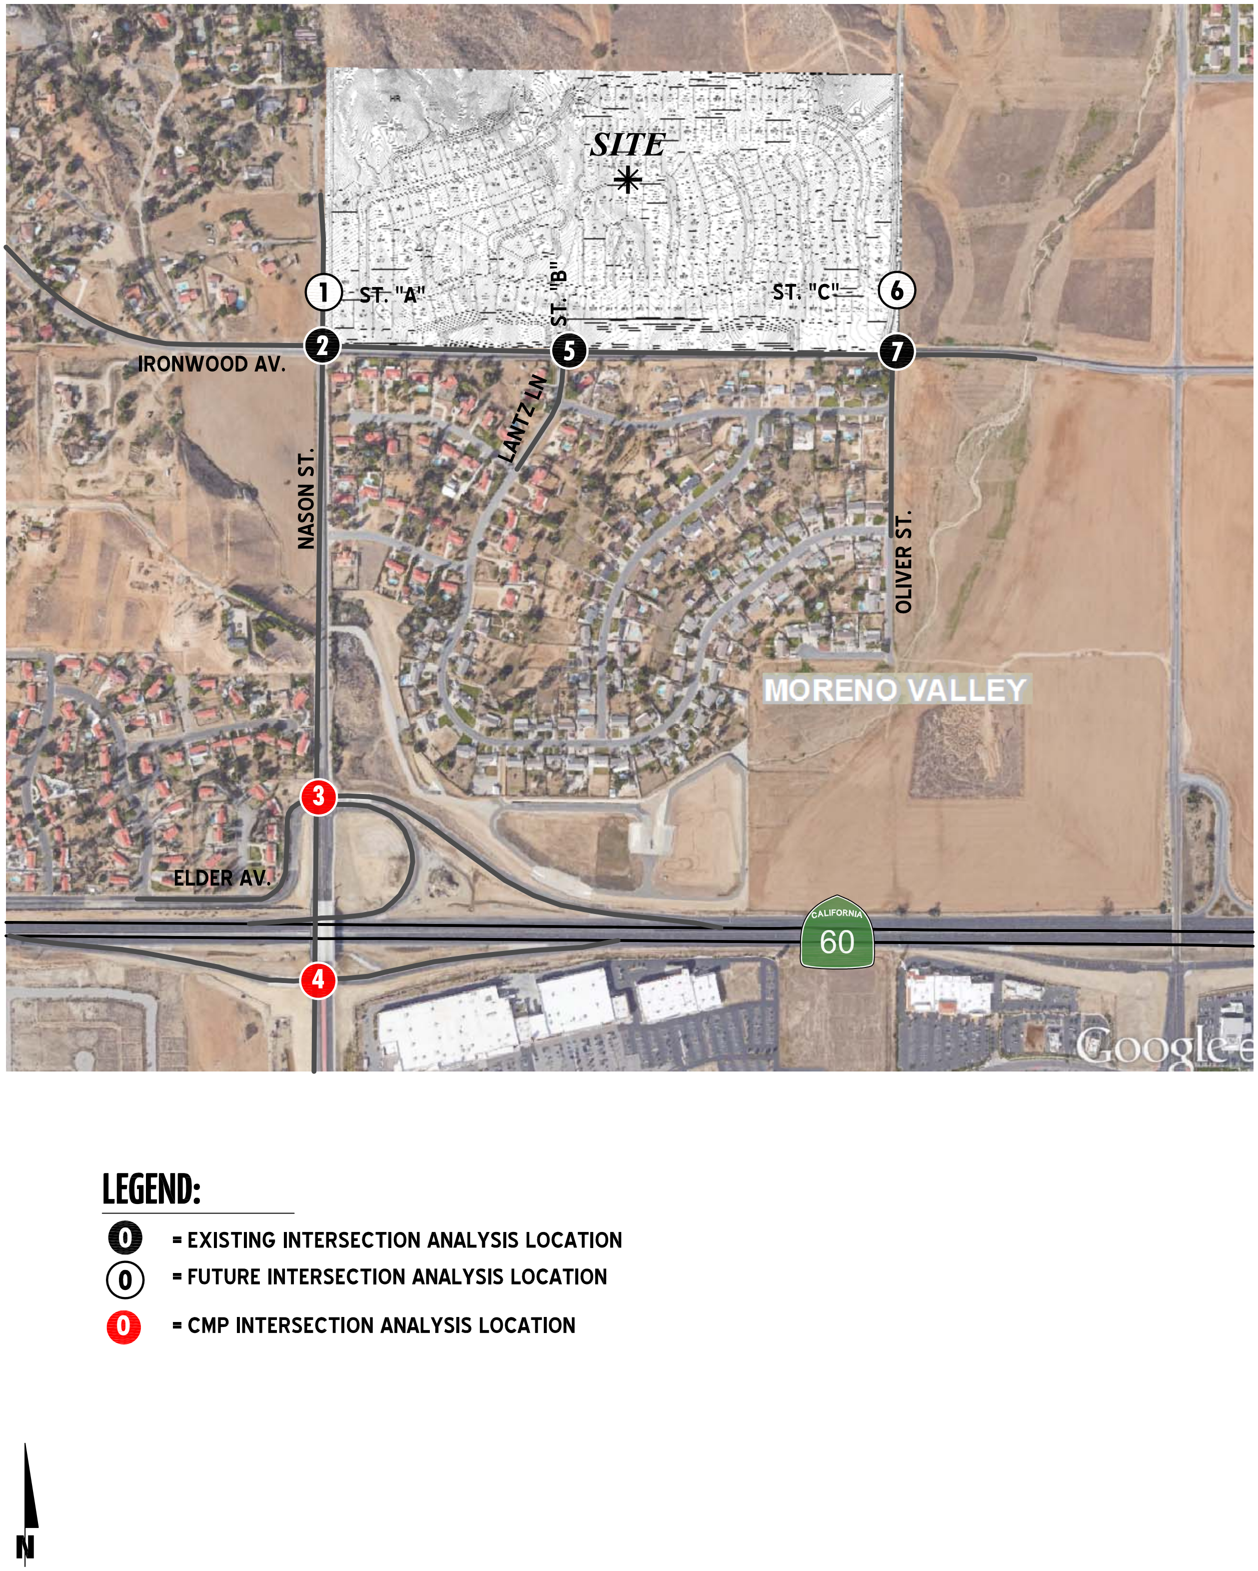
1.3 STUDY AREA

The traffic impact study area was defined in coordination with the City of Moreno Valley and in conformance with the requirements of the City's TIA preparation guidelines. Based on these guidelines, the minimum area to be studied shall include any intersection of "Collector" or higher classification street, with "Collector" or higher classification streets, at which the proposed project will add 50 or more peak hour trips. Exhibit 1-2 presents the study area roadway network and intersection analysis locations.

It should be pointed out that the "50 peak hour trip" criteria utilized by the City of Moreno Valley is consistent with the methodology employed by other jurisdictions throughout Riverside County and generally represents a threshold of trips at which a typical intersection would have the potential to be impacted. Although each intersection may have unique operating characteristics, this traffic engineering rule of thumb is a valid and proven way to establish a study area.

To ensure that this TIA satisfies the needs of the City of Moreno Valley and complies with the City's TIA preparation guidelines, Urban Crossroads, Inc. prepared a Project Traffic Study Scoping Agreement for review by City staff prior to the preparation of this TIA. The Agreement provides an outline of the Project study area, trip generation, trip distribution, and analysis methodology. The Agreement approved by the City of Moreno Valley is included in Appendix "1.1".

EXHIBIT 1-2: LOCATION MAP



1.3.1 INTERSECTIONS

The following seven Project study area intersection locations shown on Exhibit 1-2 and listed on Table 1-1 were selected for this TIA based on the City's TIA analysis methodology that requires analysis of intersection locations with 50 or more peak-hour Project trips and input from the City of Moreno Valley Traffic Engineering Division.

TABLE 1-1: INTERSECTION ANALYSIS LOCATIONS

ID	Intersection Location	Jurisdiction
1	Nason Street / Street "A" – Future Intersection	Moreno Valley
2	Nason Street / Ironwood Avenue	Moreno Valley
3	Nason Street / SR-60 Westbound Ramps	Moreno Valley, Caltrans
4	Nason Street / SR-60 Eastbound Ramps	Moreno Valley, Caltrans
5	Street "B"/Lantz Lane / Ironwood Avenue	Moreno Valley
6	Oliver Street / Street "C"	Moreno Valley
7	Oliver Street / Ironwood Avenue	Moreno Valley

1.3.2 ROADWAY SEGMENTS

The roadway segment study area utilized for this analysis is based on a review of the key roadway segments in which the Project is anticipated to contribute 50 or more peak hour trips as shown on Exhibit 1-2. The study area identifies a total of 10 existing/future roadway segments. Table 1-2 provides a summary of the study area roadway segments.

TABLE 1-2: ROADWAY SEGMENT ANALYSIS LOCATIONS

ID	Roadway Segments	Jurisdiction
1	Nason Street, Street "A" to Ironwood Avenue	Moreno Valley
2	Nason Street, South of Ironwood Avenue	Moreno Valley
3	Nason Street, North of SR-60 Westbound Ramps	Moreno Valley
4	Nason Street, SR-60 Westbound Ramps to SR-60 Eastbound Ramps	Moreno Valley
5	Nason Street South of SR-60 Eastbound Ramps	Moreno Valley
6	Ironwood Avenue, West of Nason Street	Moreno Valley
7	Ironwood Avenue, Nason Street to Lantz Lane	Moreno Valley
8	Ironwood Avenue, Lantz Lane to Oliver Street	Moreno Valley
9	Ironwood Avenue, East of Oliver Street	Moreno Valley
10	Oliver Street, Street "C" and Ironwood Avenue	Moreno Valley

1.4 CIRCULATION SYSTEM DEFICIENCIES AND RECOMMENDED IMPROVEMENTS

A summary of the operationally deficient study area intersections, deficient roadway segments, and recommended improvements required to achieve acceptable circulation system operational conditions are described in detail within Section 3.0 *Existing Conditions*, Section 5.0 *E+P Traffic Analysis*, Section 6.0 *Opening Year Cumulative (2020) Traffic Analysis*, and Section 7.0 *Horizon Year (2035) Traffic Analysis* of this report. The peak hour intersection LOS are summarized on

Table 1-3 for each of the analysis scenarios and the roadway segment LOS are summarized on Table 1-4.

Table 1-5 lists the recommended improvements necessary to reduce the identified intersection LOS deficiencies by traffic condition. Street and intersection improvements that may be funded though the City's DIF and/or TUMF programs are noted. If a particular facility tentatively listed in Table 1-5 is ultimately excluded from either the DIF or TUMF programs, the Project would be responsible for, and would be required to pay, fair share fees for improvement of affected facilities. These fees are collected as part of a funding mechanism aimed at ensuring that regional highways and arterial expansions keep pace with the projected vehicle trip increases. Alternatively, minor fair share responsibilities may be waived when collection is infeasible or where other mitigation assignments substantially exceed the Project's demonstrated impacts.

Roadway widening has been recommended consistent with the improvements necessary to achieve acceptable peak hour intersection operations (see Table 1-5), however, additional roadway widening has not been recommended if the adjacent study area intersection of the deficient roadway segment is anticipated to operate at acceptable LOS without additional through lanes.

1.5 LOCAL AND REGIONAL FUNDING MECHANISMS

Transportation improvements throughout the City of Moreno Valley are funded through a combination of project mitigation, fair share contributions or development impact fee programs, such as Transportation Uniform Mitigation Fee (TUMF) program or the County's Development Impact Fee (DIF) program. Identification and timing of needed improvements is generally determined through local jurisdictions based upon a variety of factors.

1.5.1 TRANSPORTATION UNIFORM MITIGATION FEE (TUMF) PROGRAM

The Western Riverside Council of Governments (WRCOG) is responsible for establishing and updating TUMF rates. The County may grant to developers a credit against the specific components of fees for the dedication of land or the construction of facilities identified in the list of improvements funded by each of these fee programs. Fees are based upon projected land uses and a related transportation needs to address growth based upon a 2009 Nexus study.

TUMF is an ambitious regional program created to address cumulative impacts of growth throughout western Riverside County. Program guidelines are being handled on an iterative basis. Exemptions, credits, reimbursements and local administration are being deferred to primary agencies. The County of Riverside serves this function for the proposed Project. Fees submitted to the County are passed on to the WRCOG as the ultimate program administrator.

Table 1-3

Summary of Intersection Level of Service

#	Intersection	Traffic Control[2]	Existing Level of Service		E+P Level of Service		2020 NP Level of Service		2020 WP Level of Service		2035 NP Level of Service		2035 WP Level of Service	
			AM	PM	AM	PM	AM	PM	AM	PM	AM	PM	AM	PM
1	Nason St. / Street "A"	**CSS**	NA[3]		A	A	NA[3]		A	A	NA[3]		A	A
2	Nason St. / Ironwood Av.	TS	B	B	B	B	D	C	D	C	**F**	**F**	**F**	**F**
3	Nason St. / SR-60 WB Ramps	TS	B	C	C	C	C	C	C	C	C	C	C	C
4	Nason St. / SR-60 EB Ramps	TS	B	B	B	B	C	B	C	B	C	C	C	C
5	Lantz Ln. / Ironwood Av.	CCS	B	B	B	B	B	B	B	B	B	B	C	B
6	Oliver St. / Street "C"	**CSS**	NA[3]		A	A	NA[3]		A	A	NA[3]		A	A
7	Oliver St. / Ironwood Av.	CCS	B	B	B	B	B	B	B	B	B	B	C	B

BOLD = LOS does not meet the applicable jurisdictional requirements (i.e., unacceptable LOS).

[1] Per the 2010 Highway Capacity Manual, overall average intersection delay and level of service are shown for intersections with a traffic signal or all way stop control. For intersections with cross street stop control, the delay and level of service for the worst individual movement (or movements sharing a single lane) are shown.

[2] CSS = Cross-street Stop; TS = Traffic Signal

[3] NA = Not applicable; intersection does not exist for analysis scenario.

Table 1-4

Summary of Roadway Segment Level of Service

#	Roadway	Segment Limits	Roadway Section	Existing LOS[2]	E+P LOS[2]	2020 NP LOS[2]	2020 WP LOS[2]	2035 NP LOS[2]	2035 WP LOS[2]	Acceptable LOS[2]
1	Nason Street	Street "A" to Ironwood Avenue	**2U**	NA[3]	A	NA[3]	A	NA[3]	A	C
2		South of Ironwood Avenue	2U	A	A	C	C	C	D	D
3		North of SR-60 WB Ramps	4D	A	A	A	A	A	A	D
4		SR-60 WB Ramps to SR-60 EB Ramps	4D	A	A	A	A	A	A	D
5		South of SR-60 EB Ramps	4D	A	A	B	B	C	C	D
6	Ironwood Avenue	West of Nason Street	2U	A	A	**E**	**E**	**F**	**F**	C
7		Nason Street to Lantz Lane	2U	A	A	B	B	B	C	C
8		Lantz Lane to Oliver Street	2U	A	A	A	B	B	B	C
9		East of Oliver Street	2U	A	A	A	B	B	B	C
10	Oliver Street	Between Street "C" and Ironwood Avenue	**2U**	NA[3]	A	NA[3]	A	NA[3]	A	C

BOLD = LOS does not meet the applicable jurisdictional requirements (i.e., unacceptable LOS).

N/A = Not Applicable; Segment does not exist.

[1] These maximum roadway capacities have been extracted from the City of Moreno Valley's Transportation Division's Traffic Impact Analysis Transportation Division's Traffic Impact Analysis Preparation Guidelines (August 2007). These roadway capacities are "rule of thumb" estimates for planning purposes. The LOS "E" service volumes are estimated maximum daily capacity for respective classifications. Capacity is affected by such factors as intersections (spacing, configuration and control features), degree of access control, roadway grades, design geometrics (horizontal and vertical alignment standards), sight distance, vehicle mix (truck and bus traffic) and pedestrian and bicycle traffic.

[2] LOS = Level of Service.

[3] NA = Not applicable; intersection does not exist for analysis scenario.

Table 1-5

Summary of Improvements for Horizon Year (2035) Conditions

#	Intersection Location	2035 Recommended Improvements	Program Improvements[1]	Fair Share[2]
2	Nason St. / Ironwood Av.	NBL turn lane	No	13.0%
		SBL turn lane	No	
		EBR turn lane	No	
		Modify the traffic signal to implement protected left turn phasing for the NB/SB approaches and overlap phasing on the EBR turn lane	No	

[1] Improvements included in TUMF Nexus or City of Moreno Valley DIF programs.

[2] Program improvements constructed by project may be eligible for fee credit. In lieu fee payment is at discretion of City.
Represents the fair share percentage for the Project during the most impacted peak hour.

TUMF guidelines empower a local zone committee to prioritize and arbitrate certain projects. The Project is located in the Central Zone. The zone has developed a 5-year capital improvement program to prioritize public construction of certain roads. TUMF is focused on improvements necessitated by regional growth. The SR-60/Nason Street interchange, Nason Street, and Ironwood Avenue are designated TUMF roadways/facilities within the Project's traffic study area.

1.5.2 CITY OF MORENO VALLEY DEVELOPMENT IMPACT FEE (DIF) PROGRAM

The City of Moreno Valley has created its own local Development Impact Fee (DIF) program to impose and collect fees from new residential, commercial and industrial development for the purpose of funding roadways and intersections necessary to accommodate City growth as identified in the City's General Plan Circulation Element. The City's DIF program includes facilities that are not part of, or which may exceed improvements identified and covered by the TUMF program. As a result, the pairing of the regional and local fee programs provides a more comprehensive funding and implementation plan to ensure an adequate and interconnected transportation system. Under the City's DIF program, the City may grant to developers a credit against specific components of fees when those developers construct certain facilities and landscaped medians identified in the list of improvements funded by the DIF program.

The timing to use the DIF fees is established through periodic capital improvement programs which are overseen by the City's Public Works Department. Periodic traffic counts, review of traffic accidents, and a review of traffic trends throughout the City are also periodically performed by City staff and consultants. The City uses this data to determine the timing of implementing the improvements listed in its facilities list.

The Project applicant will be subject to the City's DIF fee program, and will pay the requisite City DIF fees at the rates then in effect pursuant to the City's ordinance. The Project Applicant's payment of the requisite DIF fees at the rates then in effect pursuant to the DIF Program will mitigate its impacts to DIF-funded facilities.

1.5.3 FAIR SHARE CONTRIBUTION

Project mitigation may include a combination of fee payments to established programs (e.g., TUMF and/or DIF), construction of specific improvements, payment of a fair share contribution toward future improvements or a combination of these approaches. Improvements constructed by development may be eligible for a fee credit or reimbursement through the program where appropriate (to be determined at the City of Moreno Valley's discretion).

When off-site improvements are identified with a minor share of responsibility assigned to proposed development, the approving jurisdiction may elect to collect a fair share contribution or require the development to construct improvements. Detailed fair share calculations, for each peak hour, has been provided on Table 1-6 for the applicable deficient intersections shown previously on Table 1-5. Improvements included in a defined program and constructed by development may be eligible for a fee credit or reimbursement through the program where appropriate.

Table 1-6

Project Fair Share Calculations

#	Intersection	Existing	Project	2035 WP	Total New Traffic	Project % of New Traffic[1]
2	Nason St. / Ironwood Av.					
	AM:	955	102	1,741	786	**13.0%**
	PM:	785	136	1,789	1,004	13.5%

[1] Project percentage of new traffic between Existing (2015) and Horizon Year (2035) traffic conditions.

BOLD = Peak hour with the highest delay.

1.6 On-Site Roadway and Site Access Improvements

The Project is proposed to have access on Nason Street via Street "A", Ironwood Avenue via Street "B" (northern extension of Lantz Lane), and Oliver Street via Street "C". All Project driveways are proposed to accommodate full-access (e.g., no turning movement restrictions).

1.6.1 Site Adjacent Roadway and Site Access Improvements

The recommended site-adjacent roadway improvements for the Project are described below. These improvements need to be incorporated into the project description prior to Project approval or imposed as conditions of approval as part of the Project approval. Exhibit 1-3 illustrates the site-adjacent roadway improvement recommendations for the Project.

Exhibit 1-3 also illustrates the on-site and site adjacent recommended intersection improvements at the Project driveways. Construction of on-site and site adjacent improvements are recommended to occur in conjunction with adjacent Project development activity, or as needed for Project access purposes.

Ironwood Avenue – Ironwood Avenue is an east-west oriented roadway located along the Project's southern boundary. Construct Ironwood Avenue from Nason Street to Oliver Street at its ultimate half-section width as a minor arterial (88-foot right-of-way), in compliance with applicable City of Moreno Valley standards. Improvements along the Project's frontage (north side of Ironwood Avenue) would be those required by final conditions of approval for the proposed project and applicable City of Moreno Valley standards.

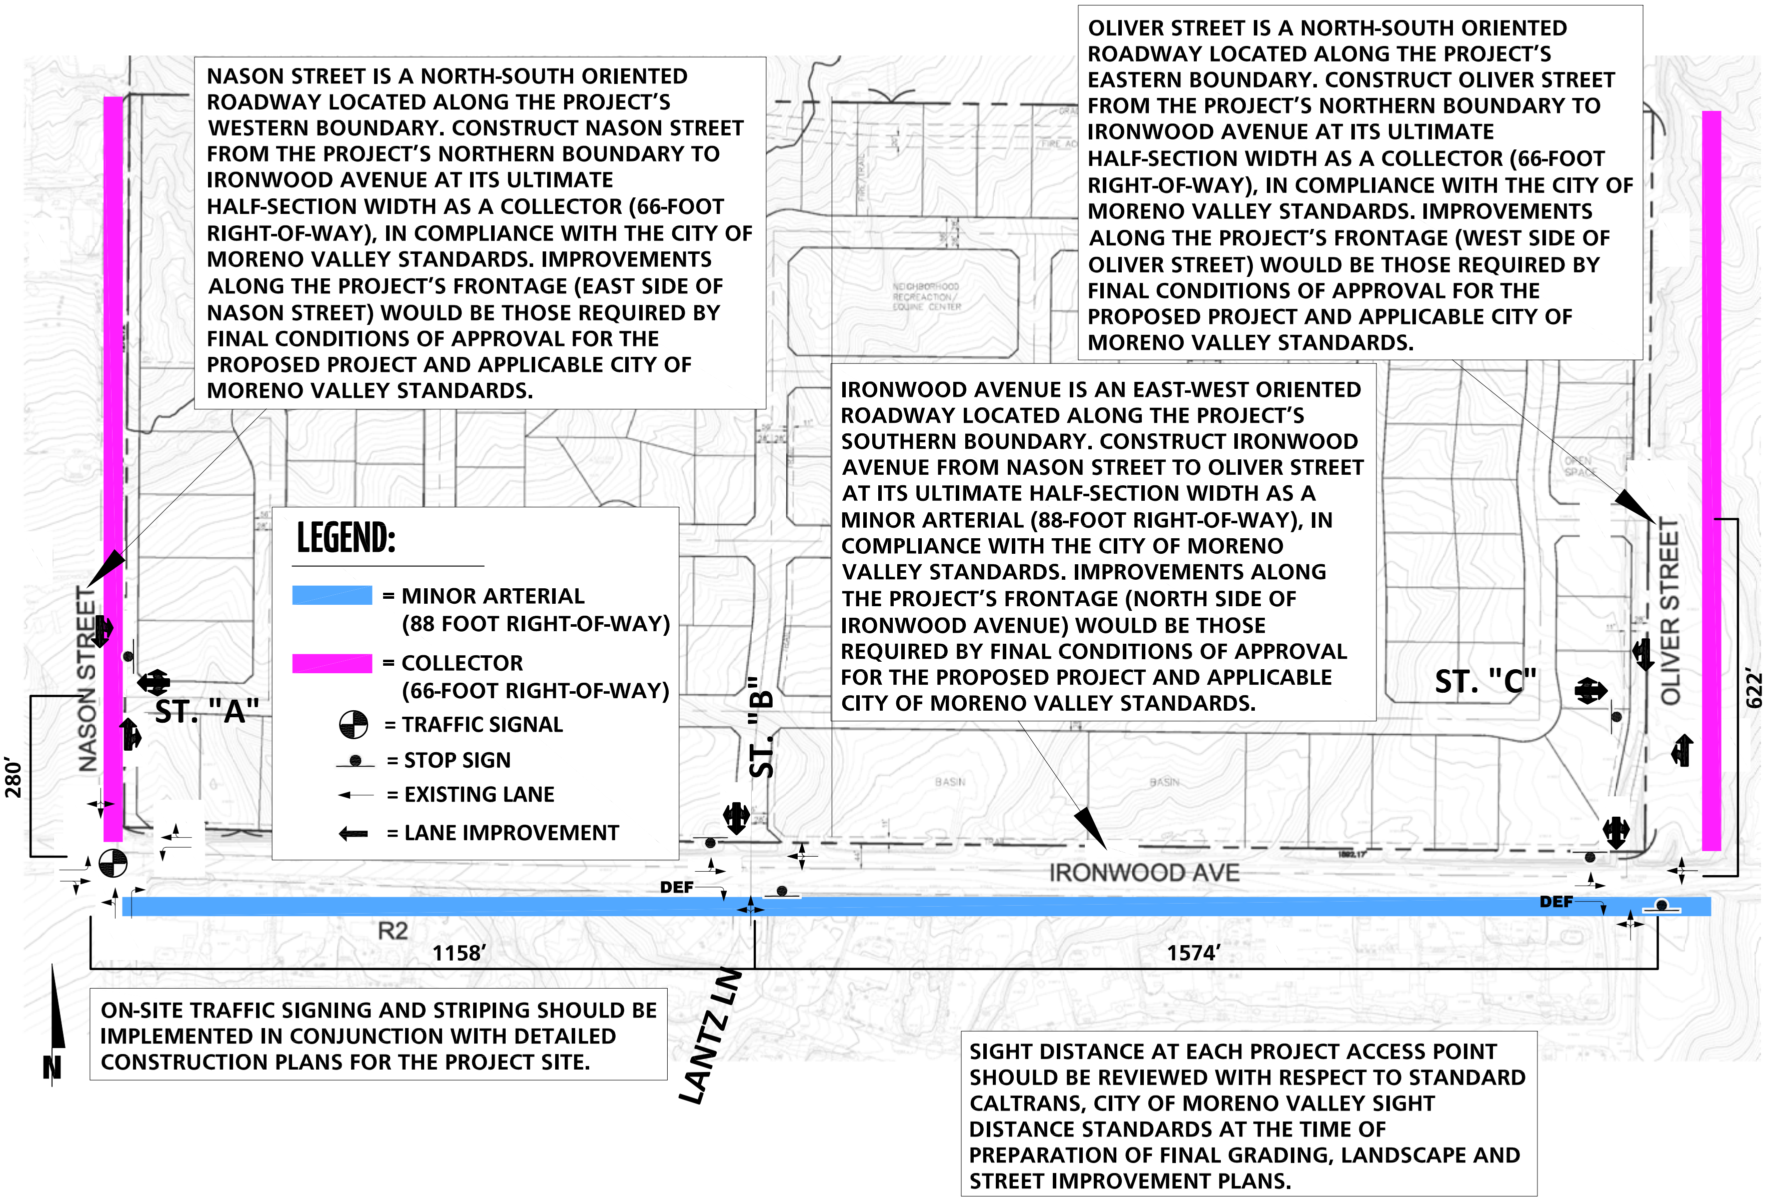
Nason Street – Nason Street is a north-south oriented roadway located along the Project's western boundary. Construct Nason Street from the Project's northern boundary to Ironwood Avenue at its ultimate half-section width as a collector (66-foot right-of-way), in compliance with applicable City of Moreno Valley standards. Improvements along the Project's frontage (east side of Nason Street) would be those required by final conditions of approval for the proposed Project and applicable City of Moreno Valley standards.

Oliver Street – Oliver Street is a north-south oriented roadway located along the Project's eastern boundary. Construct Oliver Street from the Project's northern boundary to Ironwood Avenue at its ultimate half-section width as a collector (66-foot right-of-way), in compliance with applicable City of Moreno Valley standards. Improvements along the Project's frontage (west side of Oliver Street) would be those required by final conditions of approval for the proposed Project and applicable City of Moreno Valley standards.

On-site traffic signing and striping should be implemented in conjunction with detailed construction plans for the Project site.

Sight distance at each project access point should be reviewed with respect to standard Caltrans and City of Moreno Valley sight distance standards at the time of preparation of final grading, landscape and street improvement plans.

Exhibit 1-3: Site Adjacent Roadway and Site Access Recommendations



1.7 ON-SITE TRAFFIC CALMING MEASURES

The immediate purpose of traffic calming is to reduce the speed and volume of traffic to acceptable levels (“acceptable” for the functional class of a street and the nature of bordering activity). Reductions in traffic speed and volume, however, are just means to other ends such as traffic safety and active street life. Calming traffic through the application of project design features intended to achieve slower speeds for motor vehicles, increase safety and the perception of safety for pedestrians and bicyclists, and increase access for all modes of transportation is the primary goal of any well designed residential street system.

In particular, some traffic calming elements should be incorporated in the design in and around schools to provide a comfortable and friendly environment for walking and to tightly control the behavior of cars and parents. If the school is located on a principal roadway carrying more than 4,000 vehicles per day, appropriate traffic calming features should be used to hold speeds down to 25 mph – even when children are not in school. Some typical traffic calming/management principles for school areas include: (5)

- Separate modes of transportation (i.e., cars, buses, pedestrians)
- Keep all turning movements low speed
- Provide 24-hour low speed (i.e., 25 mph or less) through design
- Provide well identified pedestrian crossings
- Give priority to pedestrians and bicyclists

The following traffic calming or traffic management design features can be used to achieve the aforementioned goals. Examples of each of the following traffic calming design features are shown on Exhibit 1-4.

1.7.1 ALL-WAY STOP CONTROL

All-way stop controls require motorists in all approaches to stop before continuing on in the direction of travel. However, implementation of an all-way stop control is only recommended if volume warrants are met.

Purpose:

- Reduce vehicle speeds
- Improve safety

Considerations:

- Potential adverse reaction by drivers due to increased delays.

Estimated Cost:

- The cost for implementation is low and requires only signage and striping.

EXHIBIT 1-4: POTENTIAL TRAFFIC CALMING MEASURES

ALL-WAY STOP

SPEED HUMPS/SPEED BUMPS

N

09386 - calming.dwg

1.7.2 Speed Humps or Speed Bumps

Speed humps are typically paved with asphalt, approximately 3-6 inches high at their center, and extend the full width of the street.

Purpose:

- Traffic calming narrow streets.
- Reducing speeds where crosswalks cross local and low-volume collector roadways.

Considerations:

- Has minimum effect on trucks and sport utility vehicles and may worsen speeding problems.
- Use when problems are very localized and can be controlled with a single measure.
- Often found to be noisy by adjacent neighbors.
- Lowest priced traffic calming features.

Estimated Cost:

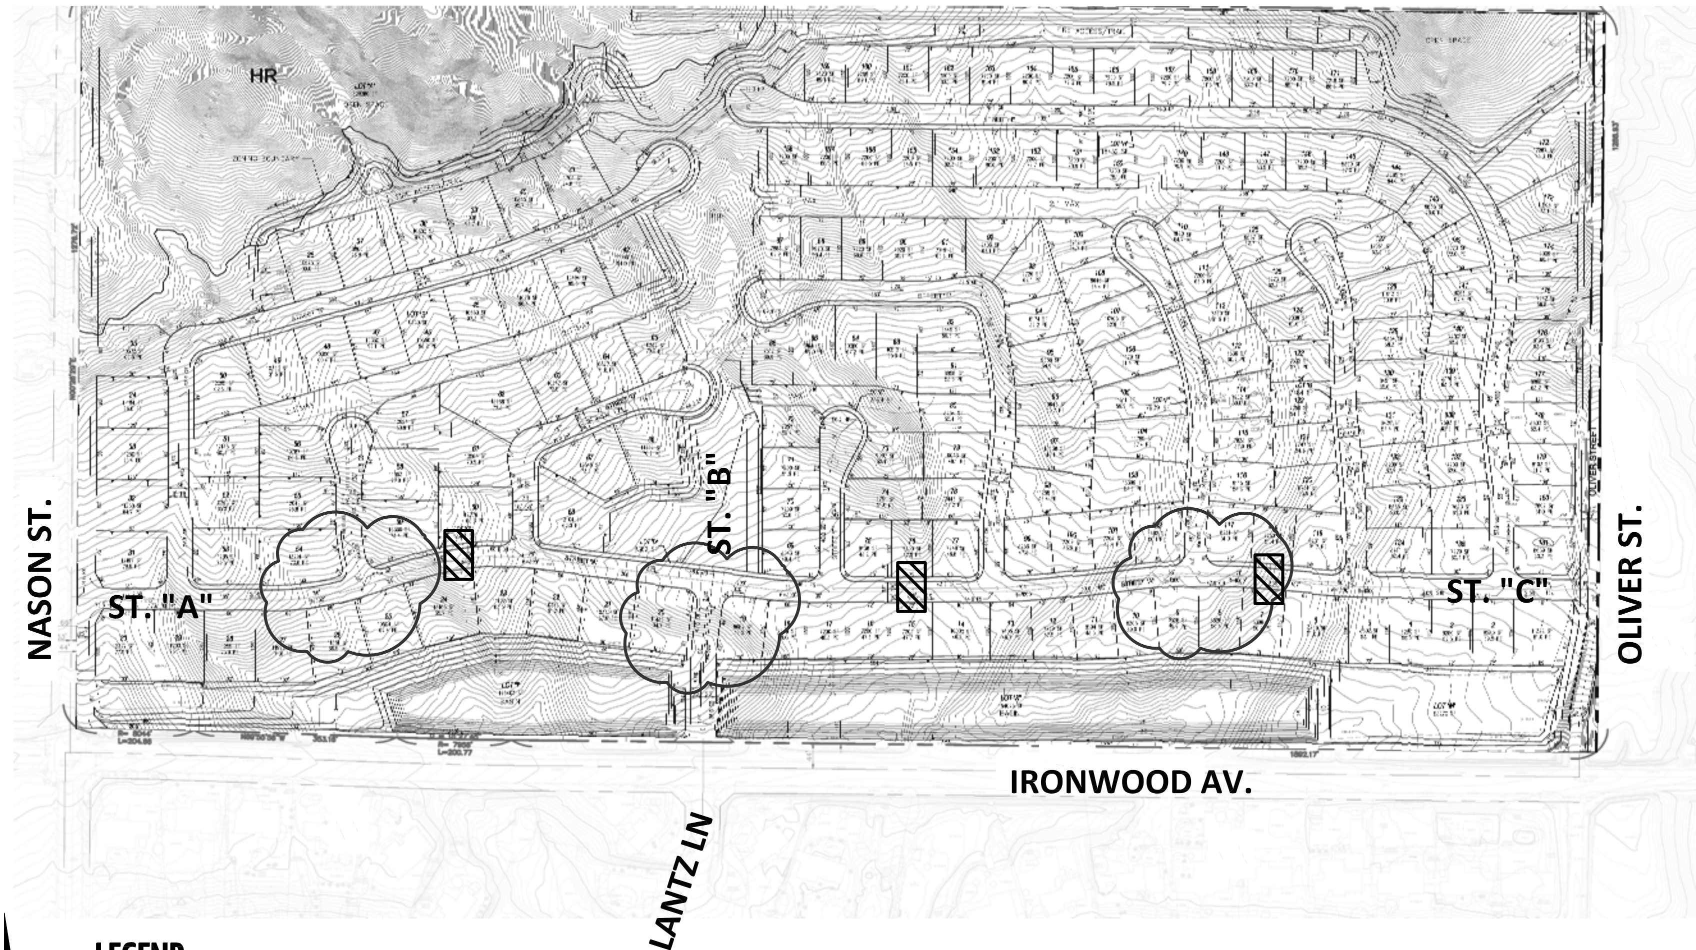
- Approximately $2,000.

1.7.3 Recommendations

As shown on Exhibit 1-5, potential all-way stop locations along Street "A" could be a relatively low cost solution to discourage speeding along this street segment, if speeding becomes an issue after the Project is constructed and occupied and appropriate warrants are met. As these particular street sections are bounded on either side by private residential units, the use of midblock chokers or street narrowing measures were considered, but have not been recommended as they would reduce the amount of on-street parking in front of nearby residential units.

Potential speed hump locations are also identified on Exhibit 1-5. No other local residential street segments were identified to require additional traffic calming design features beyond those already contemplated by the local street design.

EXHIBIT 1-5: TRAFFIC CALMING RECOMMENDATIONS



LEGEND:

= POSSIBLE SPEED HUMP LOCATION (FINAL LOCATIONS TO BE DETERMINED BY THE CITY'S TRAFFIC ENGINEER)

= POSSIBLE ALL-WAY STOP LOCATION (TO BE DETERMINED IF WARRANTED)

09386 - calming recs.dwg

2 METHODOLOGIES

This section of the report presents the methodologies used to perform the traffic analyses summarized in this report. The methodologies described are consistent with City of Moreno Valley traffic study guidelines.

2.1 LEVEL OF SERVICE

Traffic operations of roadway facilities are described using the term "Level of Service" (LOS). LOS is a qualitative description of traffic flow based on several factors such as speed, travel time, delay, and freedom to maneuver. Six levels are typically defined ranging from LOS A, representing completely free-flow conditions, to LOS F, representing breakdown in flow resulting in stop-and-go conditions. LOS E represents operations at or near capacity, an unstable level where vehicles are operating with the minimum spacing for maintaining uniform flow.

2.2 INTERSECTION CAPACITY ANALYSIS

The definitions of LOS for interrupted traffic flow (flow restrained by the existence of traffic signals and other traffic control devices) differ slightly depending on the type of traffic control. The LOS is typically dependent on the quality of traffic flow at the intersections along a roadway. The *Highway Capacity Manual* (HCM) 2010 methodology expresses the LOS at an intersection in terms of delay time for the various intersection approaches. (6) The HCM uses different procedures depending on the type of intersection control.

2.2.1 SIGNALIZED INTERSECTIONS

The City of Moreno Valley requires signalized intersection operations analysis based on the methodology described in Chapter 18 and Chapter 31 of the HCM 2010. (6) Intersection LOS operations are based on an intersection's average control delay. Control delay includes initial deceleration delay, queue move-up time, stopped delay, and final acceleration delay. For signalized intersections LOS is directly related to the average control delay per vehicle and is correlated to a LOS designation as described in Table 2-1.

TABLE 2-1: SIGNALIZED INTERSECTION HCM 2010 LOS THRESHOLDS

Description	Average Control Delay (Seconds) V/C ≤ 1.0	Level of Service V/C ≤ 1.0	Level of Service V/C > 1.0
Operations with very low delay occurring with favorable progression and/or short cycle length.	0 to 10.00	A	F
Operations with low delay occurring with good progression and/or short cycle lengths.	10.01 to 20.00	B	F
Operations with average delays resulting from fair progression and/or longer cycle lengths. Individual cycle failures begin to appear.	20.01 to 35.00	C	F
Operations with longer delays due to a combination of unfavorable progression, long cycle lengths, or high V/C ratios. Many vehicles stop and individual cycle failures are noticeable.	35.01 to 55.00	D	F
Operations with high delay values indicating poor progression, long cycle lengths, and high V/C ratios. Individual cycle failures are frequent occurrences. This is considered to be the limit of acceptable delay.	55.01 to 80.00	E	F
Operation with delays unacceptable to most drivers occurring due to over saturation, poor progression, or very long cycle lengths	80.01 and up	F	F

Source: HCM 2010, Chapter 18

All signalized study area intersections have utilized the Vistro software (Version 2.0-08), with the exception of the SR-60 Freeway ramps at Nason Street which have utilized the Synchro software (Version 8.0, Build 801, Revision 563), within the study area. Synchro is a macroscopic traffic software program that is based on the signalized intersection capacity analysis as specified in the Chapters 18 and 31 of the HCM 2010. (6) Macroscopic level models represent traffic in terms of aggregate measures for each movement at the study intersections. Equations are used to determine measures of effectiveness such as delay and queue length. The LOS and capacity analysis performed by Synchro takes into consideration optimization and coordination of signalized intersections within a network.

The LOS analysis for signalized intersections has been performed using optimal cycle lengths, splits and offsets for the study area intersections. Appropriate time for pedestrian crossings has also been considered in the signalized intersection analysis.

The peak hour traffic volumes have been adjusted using a peak hour factor (PHF) to reflect peak 15 minute volumes. Common practice for LOS analysis is to use a peak 15-mintue rate of flow. However, flow rates are typically expressed in vehicles per hour. The PHF is the relationship between the peak 15-minute flow rate and the full hourly volume (e.g. PHF = [Hourly Volume] / [4 x Peak 15-minute Flow Rate]). The use of a 15-minute PHF produces a more detailed analysis as compared to analyzing vehicles per hour. In an effort to conduct a conservative analysis, existing PHFs have been used for all analysis scenarios. Per Chapter 4 of the HCM 2010, PHF values over 0.95 often are indicative of high traffic volumes with capacity constraints on peak hour flows while lower PHF values are indicative of greater variability of flow during the peak hour. (6)

2.2.2 UNSIGNALIZED INTERSECTIONS

The City of Moreno Valley requires the operations of unsignalized intersections be evaluated using the methodology described in Chapter 19, Chapter 20, Chapter 32 of the HCM 2010. (6) The LOS rating is based on the weighted average control delay expressed in seconds per vehicle (see Table 2-2).

TABLE 2-2: UNSIGNALIZED INTERSECTION LOS THRESHOLDS

Description	Average Control Delay Per Vehicle (Seconds)	Level of Service, V/C ≤ 1.0	Level of Service, V/C > 1.0
Little or no delays.	0 to 10.00	A	F
Short traffic delays.	10.01 to 15.00	B	F
Average traffic delays.	15.01 to 25.00	C	F
Long traffic delays.	25.01 to 35.00	D	F
Very long traffic delays.	35.01 to 50.00	E	F
Extreme traffic delays with intersection capacity exceeded.	> 50.00	F	F

Source: HCM 2010, Chapter 19 and Chapter 20

At two-way or side-street stop-controlled intersections, The LOS criteria apply to each lane on a given approach and to each approach on the minor street. LOS is not calculated for major-street approaches or for the intersection as a whole. For all-way stop controlled intersections, LOS is based solely on control delay for assessment of LOS at the approach and intersection levels.

2.3 ROADWAY SEGMENT CAPACITY ANALYSIS

Roadway segment operations have been evaluated using the City of Moreno Valley Daily Roadway Capacity Values provided in the *City of Moreno Valley Transportation Engineering Division Traffic Impact Analysis (TIA) Preparation Guide* (dated August 2007). (1) Per the City of Moreno Valley TIA guidelines, roadway segments within the study area should maintain the LOS capacities illustrated on Exhibit 2-1. The daily roadway segment capacities for each type of roadway are summarized in Table 2-3. These roadway capacities are “rule of thumb” estimates for planning purposes and are affected by such factors as intersections (spacing, configuration and control features), degree of access control, roadway grades, design geometrics (horizontal and vertical alignment standards), sight distance, vehicle mix (truck and bus traffic) and pedestrian bicycle traffic. As such, where the ADT-based roadway segment analysis indicates a deficiency (unacceptable LOS), a review of the more detailed peak hour intersection analysis and progression analysis are undertaken. The more detailed peak hour intersection analysis explicitly accounts for factors that affect roadway capacity. Therefore, roadway segment widening is typically only recommended if the peak hour intersection analysis indicates the need for additional through lanes.

TABLE 2-3: ROADWAY SEGMENT CAPACITY LOS THRESHOLDS

Facility Type	Level of Service Capacity[1]				
	A	B	C	D	E
Six Lane Divided Arterial	33,900	39,400	45,000	50,600	56,300
Four Lane Divided Arterial	22,500	26,300	30,000	33,800	37,500
Four Lane Undivided Arterial	15,000	17,500	20,000	22,500	25,000
Two Lane Industrial Collector	7,500	8,800	10,000	11,300	12,500
Two Lane Undivided Residential	N/A	N/A	N/A	N/A	2,000

[1] These maximum roadway capacities have been extracted from the City of Moreno Valley's Transportation Division's TIA Preparation Guidelines (August 2007). These roadway capacities are "rule of thumb" estimates for planning purposes. The LOS "E" service volumes are estimated maximum daily capacity for respective roadway classifications. Capacity is affected by such factors as intersections (spacing, configuration and control features), degree of access control, roadway grades, design geometrics (horizontal and vertical alignment standards), sight distance, vehicle mix (truck and bus traffic) and pedestrian and bicycle traffic.

2.4 TRAFFIC SIGNAL WARRANT ANALYSIS METHODOLOGY

The term "signal warrants" refers to the list of established criteria used by Caltrans and other public agencies to quantitatively justify or ascertain the potential need for installation of a traffic signal at an otherwise unsignalized intersection. This TIA uses the signal warrant criteria presented in the latest edition of the Federal Highway Administration's (FHWA) *Manual on Uniform Traffic Control Devices (MUTCD)*, as amended by *the MUTCD 2012 California Supplement*, for all study area intersections. (7)

The signal warrant criteria for Existing conditions are based upon several factors, including volume of vehicular and pedestrian traffic, frequency of accidents, and location of school areas. Both the FHWA's *MUTCD* and the *MUTCD 2012 California Supplement* indicate that the installation of a traffic signal should be considered if one or more of the signal warrants are met. (7) Specifically, this TIA utilizes the Peak Hour Volume-based Warrant 3 as the appropriate representative traffic signal warrant analysis for Existing traffic conditions. Warrant 3 criteria are basically identical for both the FHWA's *MUTCD* and the *MUTCD 2012 California Supplement*. Warrant 3 is appropriate to use for this TIA because it provides specialized warrant criteria for intersections with rural characteristics (e.g. located in communities with populations of less than 10,000 persons or with adjacent major streets operating above 40 miles per hour). For the purposes of this study, the speed limit was the basis for determining whether Urban or Rural warrants were used for a given intersection.

Future unsignalized intersections have been assessed regarding the potential need for new traffic signals based on future average daily traffic (ADT) volumes, using the Caltrans planning level ADT-based signal warrant analysis worksheets.

Traffic signal warrant analyses were performed for the following unsignalized study area intersections listed on Table 2-4.

TABLE 2-4: TRAFFIC SIGNAL WARRANT ANALYSIS LOCATIONS

ID	Intersection Location	Jurisdiction
1	Nason Street / Street "A"	Moreno Valley
5	Street "B" / Ironwood Avenue	Moreno Valley
6	Oliver Street / Street "C"	Moreno Valley
7	Oliver Street / Ironwood Avenue	Moreno Valley

It is important to note that a signal warrant defines the minimum condition under which the installation of a traffic signal might be warranted. Meeting this threshold condition does not require that a traffic control signal be installed at a particular location, but rather, that other traffic factors and conditions be evaluated in order to determine whether the signal is truly justified. It should also be noted that signal warrants do not necessarily correlate with LOS. An intersection may satisfy a signal warrant condition and operate at or above acceptable LOS or operate below acceptable LOS and not meet a signal warrant.

2.5 LOS CRITERIA

The definition of an intersection deficiency in the City of Moreno Valley is based on the City of Moreno Valley General Plan Circulation Element. The City of Moreno Valley General Plan states that target LOS "C" or LOS "D" be maintained along City roads (including intersections) wherever possible. An exhibit depicting the level of service standards within the City was previously provided on Exhibit 2-1.

A summary of jurisdiction, LOS methodology and acceptable LOS for all the study area intersections in this TIA is shown on Table 2-5.

TABLE 2-5: SUMMARY OF LOS CRITERIA AND FOR STUDY AREA INTERSECTIONS

#	Intersection	Traffic Control[2]	Jurisdiction	LOS Methodology[1]	Acceptable LOS
1	Nason Street / Street "A"	CSS	Moreno Valley	HCM 2010	C
2	Nason Street / Ironwood Avenue	TS	Moreno Valley	HCM 2010	D
3	Nason Street / SR-60 WB Ramps	TS	Moreno Valley	HCM 2010	D
4	Nason Street / SR-60 EB Ramps	TS	Moreno Valley	HCM 2010	D
5	Lantz Lane / Ironwood Avenue	CSS	Moreno Valley	HCM 2010	C
6	Oliver Street / Street "C"	CSS	Moreno Valley	HCM 2010	C
7	Oliver Street / Ironwood Avenue	CSS	Moreno Valley	HCM 2010	C

URBAN CROSSROADS

3 AREA CONDITIONS

This section provides a summary of the existing circulation network, the City of Moreno Valley and a review of existing peak hour intersection operations, roadway segment analyses, and traffic signal warrants.

3.1 EXISTING CIRCULATION NETWORK

The study area includes a total of seven existing and future intersections as shown previously on Exhibit 1-2. Of these seven intersections, the existing study area circulation network includes five intersections. Nason Street / Street “A” and Oliver Street / Street “C” are planned future intersections that do not currently exist. Exhibit 3-1 illustrates the study area intersections located near the proposed Project and identifies the number of through traffic lanes for existing roadways and intersection traffic controls.

3.2 CITY OF MORENO VALLEY GENERAL PLAN CIRCULATION ELEMENT

As previously noted, the Project site is located within the City of Moreno Valley. Exhibit 3-2 shows the City of Moreno Valley General Plan Circulation Element. Exhibit 3-3 shows the City of Moreno Valley’s General Plan Roadway Cross-Sections.

3.3 TRANSIT SERVICE

The study area is currently not being served by any direct transit line. The Riverside Transit Agency (RTA) has existing bus services running along Nason Street, south of the SR-60 Freeway via Route 210. The existing Route 210 is illustrated on Exhibit 3-4. Transit service is reviewed and updated by RTA periodically to address ridership, budget and community demand needs. Changes in land use can affect these periodic adjustments which may lead to either enhanced or reduced service where appropriate. As such, it is recommended that the applicant work in conjunction with RTA to potentially provide bus service to the site.

3.4 BICYCLE & PEDESTRIAN FACILITIES

Field observations conducted in January 2015 indicate nominal pedestrian and bicycle activity within the study area. Existing pedestrian facilities (sidewalk and crosswalk) locations within the study area are shown on Exhibit 3-5. The City of Moreno Valley’s Master Plan of Trails is shown on Exhibit 3-6. As shown on Exhibit 3-6, there are proposed trails along Ironwood Avenue east of Nason Street and along Oliver Street.

Class I bikeways are off-road bicycle and pedestrian facilities. Class II bikeways are intended to delineate the right-of-way assigned to bicyclists and motorists, and to provide for more predictable movements. Bike lane signs and pavement marking help define the type of bikeway. Class II bikeways are on-road, but are not delineated through pavement markings and only through signage. A more important reason for bike lanes is to better accommodate bicyclists through corridors where insufficient room exists for safe bicycling on existing streets.

There are existing Class II bike lanes on Nason Street south of the SR-60 WB Ramps interchange. Class II bikeways are proposed along Nason Street (south of Ironwood Avenue), Ironwood Avenue. The City of Moreno Valley's Bike Plan is shown on Exhibit 3-7.

3.5 EXISTING TRAFFIC COUNTS

The AM peak hour traffic volumes were determined by counting traffic volumes in the two hour period between 7:00 and 9:00 AM on January 29, 2015. Similarly, the PM peak hour traffic volumes were identified by counting traffic volumes in the two-hour period from 4:00 to 6:00 PM on January 29, 2015. The January 29, 2015 (Thursday) count data is representative of typical weekday peak hour traffic conditions in the study area. There were no observations made in the field that would indicate a typical traffic conditions on this date, such as construction activity or detour routes. All near-by schools were in session and operating on normal bell schedules. The raw manual peak hour turning movement traffic count data sheets are included in Appendix "3.1". Where actual 24-hour tube count data was not available, Existing ADT volumes were based upon factored intersection peak hour counts collected by Urban Crossroads, Inc. using the following formula for each intersection leg:

Weekday PM Peak Hour (Approach Volume + Exit Volume) x 10.0210

It should be noted that for those roadway segments which have 24-hour tube count data available (as provided in Appendix "3.1"), a comparison between the PM peak hour and daily traffic volumes indicated that the peak-to-daily relationship was approximately 9.80 percent (i.e., the PM peak hour volumes are approximately ten percent of the total daily traffic volume). As such, the above equation utilizing a factor of 10 estimated the ADT volumes on the study area roadway segments assuming a peak-to-daily relationship of 9.80 percent (i.e., 1/0.100210 = 9.80). Existing ADT, AM and PM peak hour intersection volumes are shown on Exhibit 3-8.

3.6 EXISTING CONDITIONS INTERSECTION OPERATIONS ANALYSIS

Existing peak hour traffic operations have been evaluated for the study area intersections based on the analysis methodologies presented in Section 2.2 *Intersection Capacity Analysis* of this report. The intersection operations analysis results are summarized in Table 3-1 which indicates that the existing study area intersections are currently operating at an acceptable LOS during the peak hours, based on applicable jurisdiction's LOS criteria.

Consistent with Table 3-1, a summary of the peak hour intersection LOS for Existing conditions are shown on Exhibit 3-9. The intersection operations analysis worksheets are included in Appendix "3.2" of this TIA.

Exhibit 3-9: Summary of Peak Hour Intersection LOS for Existing (2015) Conditions

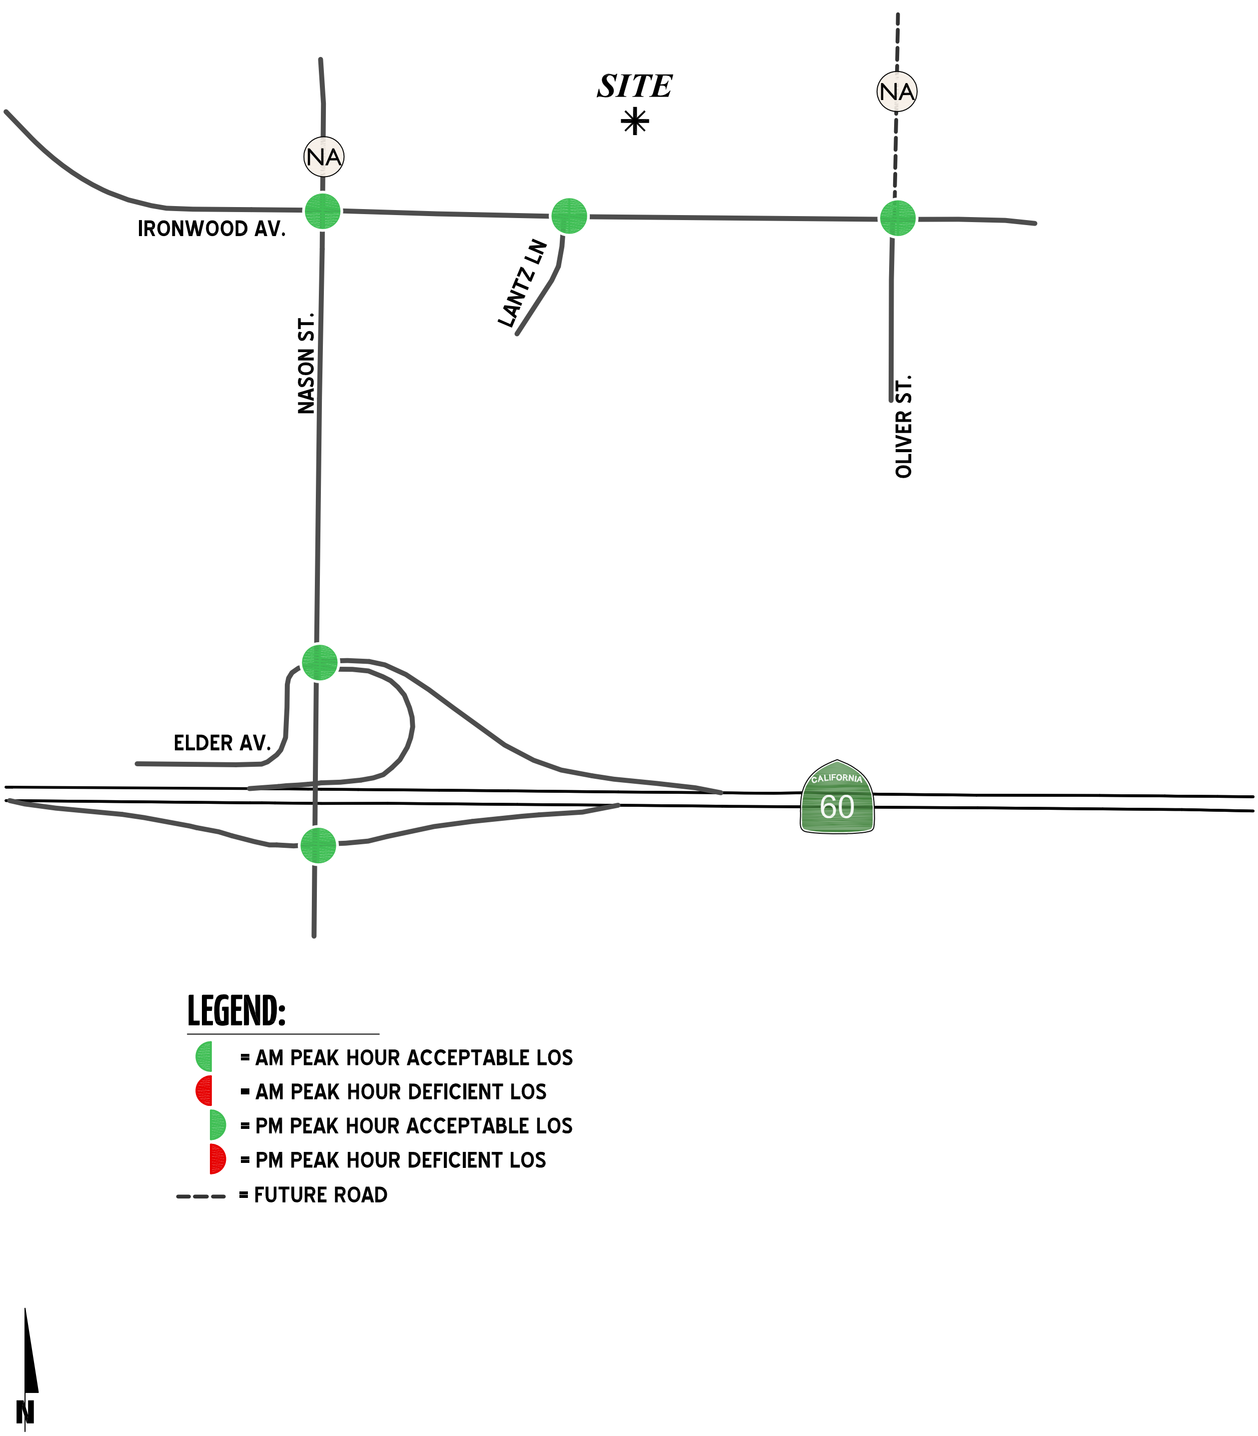

Table 3-1

Intersection Analysis for Existing (2015) Conditions

#	Intersection	Traffic Control[3]	Intersection Approach Lanes[1]												Delay[2] (secs.)		Level of Service	
			Northbound			Southbound			Eastbound			Westbound						
			L	T	R	L	T	R	L	T	R	L	T	R	AM	PM	AM	PM
1	Nason St. / Street "A"		Future Intersection															
2	Nason St. / Ironwood Av.	TS	0	1	1	0	1	0	1	1	0	1	1	0	18.1	16.7	B	B
3	Nason St. / SR-60 WB Ramps	TS	1	2	1>	1	2	0	1	1	1>	1	1	1>	19.1	20.3	B	C
4	Nason St. / SR-60 EB Ramps	TS	0	2	0	1	2	0	1	1	1	0	0	0	11.9	14.1	B	B
5	Lantz Ln. / Ironwood Av.	CCS	0	1	0	0	0	0	0	1	d	0	1	0	11.6	11.0	B	B
6	Oliver St. / Street "C"		Future Intersection															
7	Oliver St. / Ironwood Av.	CCS	0	1	0	0	1	0	0	1	d	0	1	0	11.5	11.2	B	B

BOLD = LOS does not meet the applicable jurisdictional requirements (i.e., unacceptable LOS).

[1] When a right turn is designated, the lane can either be striped or unstriped. To function as a right turn lane there must be sufficient width for right turning vehicles to travel outside the through lanes.

L = Left; T = Through; R = Right; > = Right-Turn Overlap Phasing; d= Defacto Right Turn Lane

[2] Per the 2010 Highway Capacity Manual, overall average intersection delay and level of service are shown for intersections with a traffic signal or all way stop control. For intersections with cross street stop control, the delay and level of service for the worst individual movement (or movements sharing a single lane) are shown.

[3] CSS = Cross-street Stop; TS = Traffic Signal

3.7 EXISTING CONDITIONS ROADWAY SEGMENT CAPACITY ANALYSIS

The City of Moreno Valley General Plan Circulation Element provides roadway volume capacity values presented previously on Table 2-3. The roadway segment capacities are approximate figures only, and are used at the General Plan level to assist in determining the roadway functional classification (number of through lanes) needed to meet traffic demand. Table 3-2 provides a summary of the Existing conditions roadway segment capacity analysis based on the City of Moreno Valley General Plan Circulation Element Roadway Segment Capacity (LOS) Thresholds identified previously on Table 2-3. As shown on Table 3-2, all of the study area segments currently operate at acceptable LOS based on the City's planning level daily roadway capacity thresholds.

3.8 EXISTING CONDITIONS TRAFFIC SIGNAL WARRANTS ANALYSIS

Traffic signal warrants for Existing traffic conditions are based on existing peak hour intersection turning volumes. For Existing traffic conditions, no study area intersections appear to currently warrant a traffic signal (See Appendix "3.3").

3.9 EXISTING CONDITIONS OFF-RAMP QUEUING ANALYSIS

A queuing analysis was performed for the off-ramps at the SR-60 Freeway at Nason Street interchange to assess vehicle queues for the off ramps that may potentially result in deficient peak hour operations at the ramp-to-arterial intersections and may potentially "spill back" onto the SR-60 Freeway mainline. Queuing analysis findings are presented in Table 3-3. It is important to note that off-ramp lengths are consistent with the measured distance between the intersection and the freeway mainline. As shown on Table 3-3, there are no queuing issues during the peak 95th percentile traffic flows under Existing traffic conditions. Worksheets for Existing traffic conditions off-ramp queuing analysis are provided in Appendix "3.4".

Table 3-2

Roadway Volume/Capacity Analysis for Existing (2015) Conditions

#	Roadway	Segment Limits	Roadway Section	LOS Capacity[1]	Existing (2015)	V/C	LOS	Acceptable LOS
1	Nason Street	Street "A" to Ironwood Avenue			N/A			C
2		South of Ironwood Avenue	2U	12,500	4,306	0.34	A	D
3		North of SR-60 WB Ramps	4D	37,500	4,760	0.38	A	D
4		SR-60 WB Ramps to SR-60 EB Ramps	4D	37,500	12,687	0.34	A	D
5		South of SR-60 EB Ramps	4D	37,500	17,807	0.47	A	D
6	Ironwood Avenue	West of Nason Street	2U	12,500	6,754	0.54	A	C
7		Nason Street to Lantz Lane	2U	12,500	4,568	0.37	A	C
8		Lantz Lane to Oliver Street	2U	12,500	4,279	0.34	A	C
9		East of Oliver Street	2U	12,500	4,319	0.35	A	C
10	Oliver Street	Between Street "C" and Ironwood Avenue			N/A			C

BOLD = LOS does not meet the applicable jurisdictional requirements (i.e., unacceptable LOS).

N/A = Not Applicable; Segment does not exist.

[1] These maximum roadway capacities have been extracted from the City of Moreno Valley's Transportation Division's Traffic Impact Analysis
Transportation Division's Traffic Impact Analysis Preparation Guidelines (August 2007). These roadway capacities are "rule of thumb" estimates for planning purposes. The LOS "E" service volumes are estimated maximum daily capacity for respective classifications. Capacity is affected by such factors as intersections (spacing, configuration and control features), degree of access control, roadway grades, design geometrics (horizontal and vertical alignment standards), sight distance, vehicle mix (truck and bus traffic) and pedestrian and bicycle traffic.

Table 3-3

Peak Hour Freeway Off-Ramp Queuing Summary for Existing (2015) Conditions

Intersection	Movement	Available Stacking Distance (Feet)	95th Percentile Queue (Feet) [2]		Acceptable? [1]	
			AM Peak Hour	PM Peak Hour	AM	PM
Nason St. / SR-60 WB Ramps	WBL	1,370	83	132	Yes	Yes
	WBT	2,140	21	31	Yes	Yes
	WBR	190	0	0	Yes	Yes
Nason St. / SR-60 EB Ramps	EBL	805	27	96	Yes	Yes
	EBT	1,300	46	66	Yes	Yes
	EBR	225	45	63	Yes	Yes

[1] Stacking Distance is acceptable if the required stacking distance is less than or equal to the stacking distance provided. An additional 15 feet of stacking which is assumed to be provided in the transition for turn pockets is reflected in the stacking distance shown on this table, where applicable.

[2] Maximum queue length for the approach reported.

This Page Intentionally Left Blank

4 PROJECTED FUTURE TRAFFIC

This section presents the traffic volumes estimated to be generated by the Project, as well as the Project's trip assignment onto the study area roadway network. The Project is located east of Nason Street and north of Ironwood Avenue in the City of Moreno Valley, and is proposed to consist of 181 single family detached residential dwelling units. For the purposes of this traffic study, the Project is assumed to be built and fully occupied by Year 2020.

The Project is proposed to have access on Nason Street via Street "A", Ironwood Avenue via Street "B" (northern extension of Lantz Lane), and Oliver Street via Street "C". All Project driveways are proposed to accommodate full-access (e.g., no turning movement restrictions).

4.1 PROJECT TRIP GENERATION

Trip generation represents the amount of traffic which is both attracted to and produced by a development. Determining traffic generation for a specific project is therefore based upon forecasting the amount of traffic that is expected to be both attracted to and produced by the specific land uses being proposed for a given development.

Trip generation rates used to estimate Project traffic and a summary of Project's trip generation are shown in Table 4-1. The trip generation rates are based upon data collected by the Institute of Transportation Engineers (ITE) and presented in ITE's most recent edition of *Trip Generation* manual. (2)

The Project is anticipated to generate a net total of approximately 1,723 trip-ends per day with 136 AM peak hour trips and 181 PM peak hour trips.

4.2 PROJECT TRIP DISTRIBUTION

Trip distribution is the process of identifying the probable destinations, directions or traffic routes that will be utilized by Project traffic. The potential interaction between the planned land uses and surrounding regional access routes are considered, to identify the route where the Project traffic would distribute. The Project trip distribution was developed based on anticipated travel patterns to and from the Project site for the traffic associated with the proposed residential use.

The total volume on each roadway was divided by the total site traffic generation to indicate the percentage of Project traffic that would use each component of the regional roadway system in each relevant direction. The Project trip distribution patterns are graphically depicted on Exhibit 4-1.

4.3 MODAL SPLIT

The traffic reducing potential of public transit, walking or bicycling have not been considered in this TIA. Essentially, the traffic projections are "conservative" in that these alternative travel modes might be able to reduce the forecasted traffic volumes.

Table 4-1

Project Trip Generation Summary

Land Use	ITE Code	Units[2]	AM Peak Hour			PM Peak Hour			Daily
			In	Out	Total	In	Out	Total	
Project Trip Generation Rates[1]									
Single Family Detached Residential	210	DU	0.19	0.56	0.75	0.63	0.37	1.00	9.52

Land Use	Quantity	Units[2]	AM Peak Hour			PM Peak Hour			Daily
			In	Out	Total	In	Out	Total	
Project Trip Generation Summary									
Single Family Detached Residential	181	DU	34	102	136	114	67	181	1,723

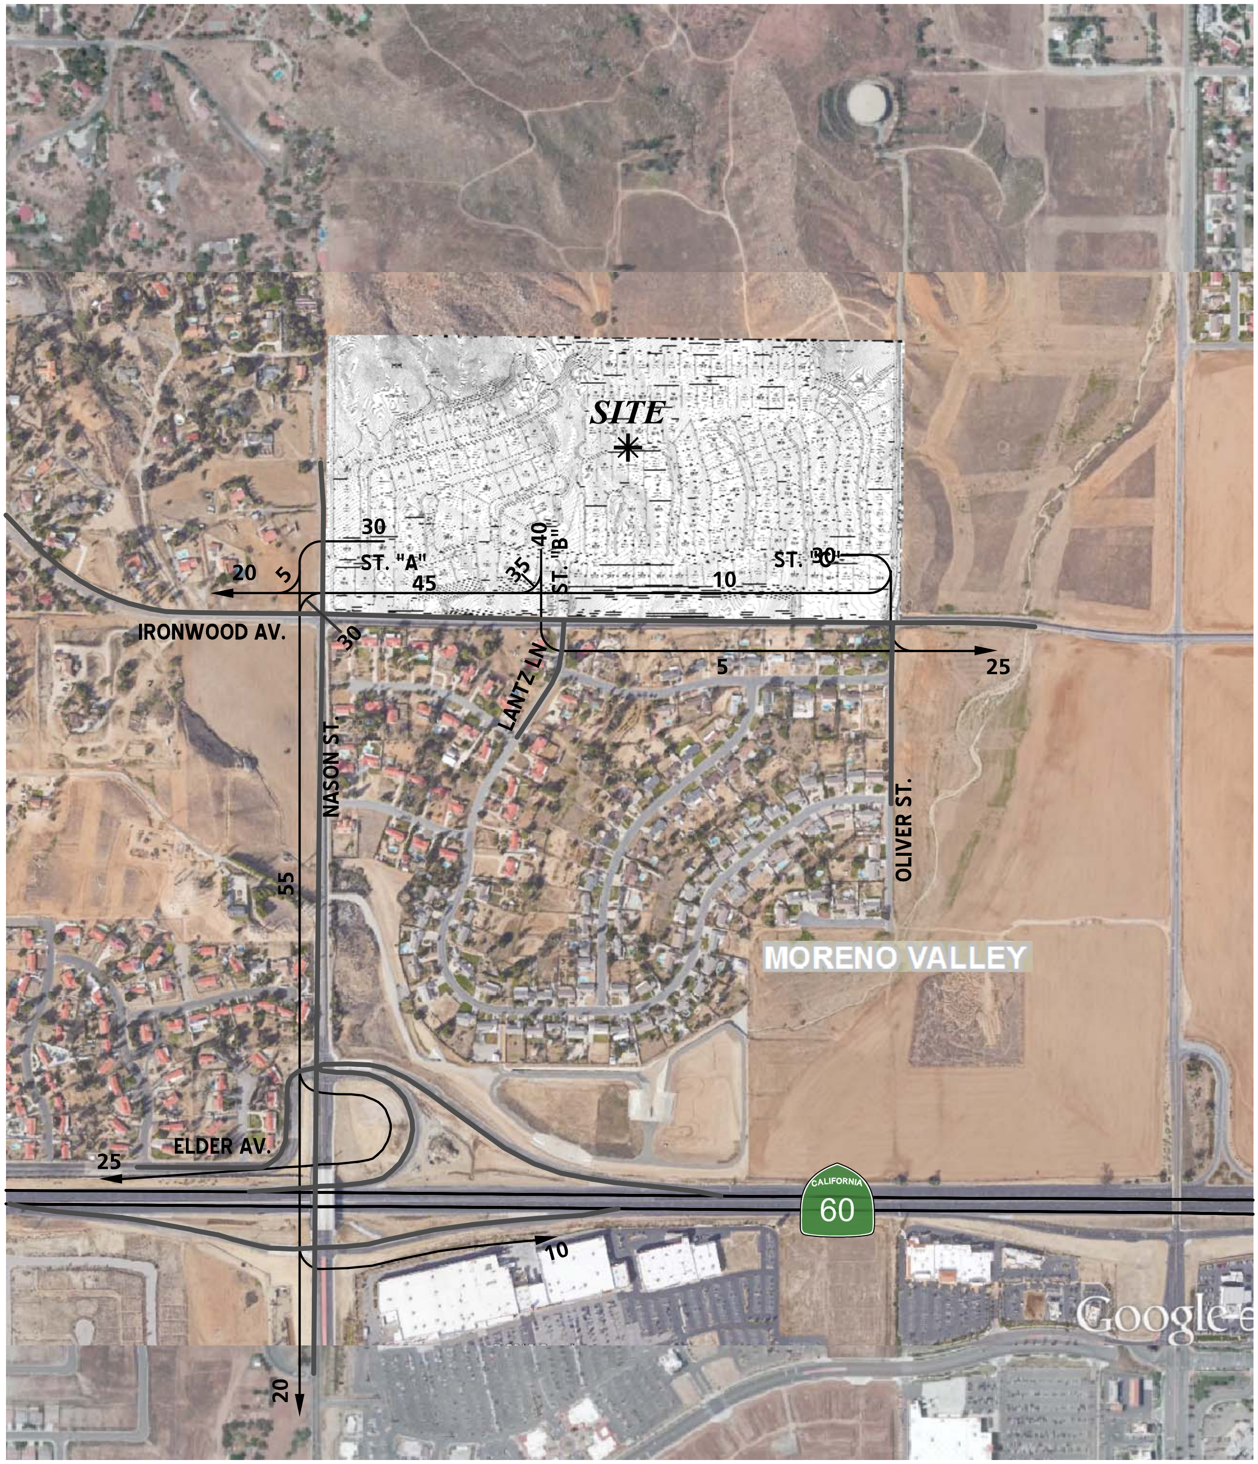
[2] DU = Dwelling Units

EXHIBIT 4-1: PROJECT TRIP DISTRIBUTION



LEGEND:

10 = PERCENT TO/FROM PROJECT

N

4.4 PROJECT TRIP ASSIGNMENT

The assignment of traffic from the Project area to the adjoining roadway system is based upon the Project trip generation, trip distribution, and the arterial highway and local street system improvements that would be in place by the time of initial occupancy of the Project. Based on the identified Project traffic generation and trip distribution patterns, Project ADT, AM and PM peak hour traffic volumes are shown on Exhibit 4-2.

4.5 BACKGROUND TRAFFIC

Future year traffic forecasts have been based upon five (5) years of background (ambient) growth at 2% per year for 2020 traffic conditions. The ambient growth factor is intended to approximate regional traffic growth. The total ambient growth is 10.41% for 2020 traffic conditions (compounded growth of two percent per year over five years or $1.02^{5\ \text{years}}$). This ambient growth rate is added to existing traffic volumes to account for area-wide growth not reflected by cumulative development projects. Ambient growth has been added to daily and peak hour traffic volumes on surrounding roadways, in addition to traffic generated by the development of future projects, located within or in close proximity to the study area, that have been approved but not yet built and/or for which development applications have been filed and are under consideration by governing agencies.

4.6 CUMULATIVE DEVELOPMENT TRAFFIC

CEQA guidelines require that other reasonably foreseeable development projects which are either approved or being processed concurrently in the study area also be included as part of a cumulative analysis scenario. A cumulative project list was developed for the purposes of this analysis through consultation with planning and engineering staff from the City of Moreno Valley and adjacent jurisdictions. Exhibit 4-3 illustrates the cumulative development location map. A summary of cumulative development projects and their proposed land uses are shown on Table 4-2. If applicable, the traffic generated by individual cumulative projects was manually added to the Opening Year and Horizon Year forecasts to ensure that traffic generated by the listed cumulative development projects in Table 4-2 are reflected as part of the background traffic.

4.7 OPENING YEAR CUMULATIVE (2020) CONDITIONS

To provide a comprehensive assessment of potential transportation network deficiencies, two types of analyses, “buildup” and “buildout”, were performed in support of this work effort. The “buildup” method was used to approximate the Opening Year Cumulative traffic forecasts, and is intended to identify the cumulative impacts on both the existing and planned near-term circulation system. The Opening Year Cumulative traffic forecasts include background traffic, traffic generated by other cumulative development projects within the study area, and the traffic generated by the proposed Project. The “buildout” approach is used to forecast the Horizon Year Without and With Project conditions of the study area.

[4] Source: March Lifecare Campus Specific Plan Traffic Impact Analysis, Mountain Pacific, Inc., May 2009 (Revised).

The buildup approach combines existing traffic counts with a background ambient growth factor and cumulative development traffic to forecast the Opening Year Cumulative traffic conditions. An ambient growth factor of 10.41% accounts for background (area-wide) traffic increases that occur over time up to the year 2020 from the year 2015 (compounded two percent per year growth over a minimum five year period). Traffic volumes generated by the Project are then added to assess the Opening Year Cumulative With Project traffic conditions. The Opening Year roadway network is similar to the Existing conditions roadway network, with the exception of future driveways proposed to be developed by the Project.

The near-term traffic analysis includes the following traffic conditions, with the various traffic components:

- Opening Year Cumulative (2020) Without Project
  - Existing 2015 counts
  - Ambient growth traffic (10.41%)
  - Cumulative Development traffic
- Opening Year Cumulative (2020) With Project
  - Existing 2015 counts
  - Ambient growth traffic (10.41%)
  - Cumulative Development traffic
  - Project traffic

4.8 HORIZON YEAR (2035) VOLUME DEVELOPMENT

The Horizon Year (2035) Without Project traffic conditions were derived from the Riverside County Transportation Analysis Model (RivTAM) modified to represent General Plan Buildout conditions for the City of Moreno Valley using accepted procedures for model forecast refinement and smoothing. The traffic forecasts reflect the area-wide growth anticipated between Existing conditions and General Plan Buildout conditions.

In most instances the traffic model zone structure is not designed to provide accurate turning movements along arterial roadways unless refinement and reasonableness checking is performed. Therefore, the Horizon Year Without Project peak hour forecasts were refined using the model derived long-range forecasts, along with existing peak hour traffic count data collected at each analysis location in January 2015. Future estimated peak hour traffic data was used for new intersections and intersections with an anticipated change in travel patterns to further refine the Horizon Year With Project peak hour forecasts.

The refined future peak hour approach and departure volumes obtained from the model output data are then entered into a spreadsheet program consistent with the National Cooperative Highway Research Program (NCHRP Report 255), along with initial estimates of turning movement proportions. A linear programming algorithm is used to calculate individual turning movements which match the known directional roadway segment forecast volumes computed in the previous step. This program computes a likely set of intersection turning movements from intersection approach counts and the initial turning proportions from each approach leg.

Typically, the model growth is prorated and is subsequently added to the existing (base validation) traffic volumes to represent Horizon Year traffic conditions. However, review of the resulting model growth indicates negative growth for several study area intersections. In an effort to conduct a conservative analysis, reductions to traffic forecasts from either Existing or Opening Year Cumulative traffic conditions were not assumed as part of this analysis. As such, in conjunction with the addition of cumulative projects that are not consistent with the General Plan, additional growth has also been applied on a movement-by-movement basis, where applicable, to estimate reasonable Horizon Year forecasts. Horizon Year turning volumes were compared to Opening Year Cumulative volumes in order to ensure a minimum growth as a part of the refinement process. The minimum growth includes any additional growth between Opening Year Cumulative and Horizon Year traffic conditions that is not accounted for by the traffic generated by cumulative development projects and ambient growth rates assumed between Existing (2015) and Opening Year Cumulative traffic conditions. Future estimated peak hour traffic data was used for new intersections and intersections with an anticipated change in travel patterns to further refine the Horizon Year peak hour forecasts.

The future Horizon Year Without Project peak hour turning movements were then reviewed by Urban Crossroads for reasonableness, and in some cases, were adjusted to achieve flow conservation, reasonable growth, and reasonable diversion between parallel routes. Flow conservation checks ensure that traffic flow between two closely spaced intersections, such as two freeway ramp locations, is verified in order to make certain that vehicles leaving one intersection are entering the adjacent intersection and that there are no unexplained loss of vehicles. The result of this traffic forecasting procedure is a series of traffic volumes which are suitable for traffic operations analysis.

Post-processing worksheets for Horizon Year Without Project traffic conditions are provided in Appendix 4.1.

5 EXISTING PLUS PROJECT TRAFFIC ANALYSIS

In an effort to satisfy the CEQA Guideline section 15125(a), an analysis of existing traffic volumes plus traffic generated by the proposed Project (E+P) has been included in this analysis. This section discusses the traffic forecasts for E+P conditions and the resulting intersection operations, roadway segment analyses, and traffic signal warrants.

5.1 ROADWAY IMPROVEMENTS

The lane configurations and traffic controls assumed to be in place for E+P conditions are consistent with those shown previously on Exhibit 3-1, with the exception of Project streets assumed to be constructed by the Project to provide site access. In other words, no other off-site improvements are assumed beyond those that currently exist with the exception of the intersections and roadways that would be improved by the Project for access.

5.2 EXISTING PLUS PROJECT TRAFFIC VOLUME FORECASTS

This scenario includes Existing traffic volumes plus Project traffic. Exhibit 5-1 shows the ADT, AM and PM peak hour traffic volumes which can be expected for E+P traffic conditions.

5.3 INTERSECTION OPERATIONS ANALYSIS

E+P peak hour traffic operations have been evaluated for the study area intersections based on the analysis methodologies presented in Section 2 *Methodologies* of this TIA. The intersection analysis results are summarized in Table 5-1, which indicates all study area intersections are anticipated to continue to operate at acceptable LOS consistent with Existing traffic conditions. As such, the addition of Project traffic is not anticipated to result in any deficiencies.

Consistent with Table 5-1, a summary of the peak hour intersection LOS for E+P conditions are shown on Exhibit 5-2. The intersection operations analysis worksheets for E+P traffic conditions are included in Appendix “5.1” of this TIA.

5.4 ROADWAY SEGMENT CAPACITY ANALYSIS

Table 5-2 provides a summary of the E+P conditions roadway segment capacity analysis based on the City of Moreno Valley General Plan Circulation Element Roadway Segment Capacity/(LOS) Thresholds identified previously on Table 2-3. As shown on Table 5-2, all the study roadway segments are anticipated to operate at acceptable LOS consistent with Existing traffic conditions. As such, the addition of Project traffic is not anticipated to result in any deficiencies.

5.5 TRAFFIC SIGNAL WARRANTS ANALYSIS

Traffic signal warrants for E+P traffic conditions are based on both E+P Caltrans planning-level ADT and peak hour volumes. For E+P conditions, there are no traffic signals that appear to be warranted (see Appendix “5.2”).

10	Oliver Street	Between Street "C" and Ironwood Avenue	**2U**	2,000	N/A			517	0.26	A	C

BOLD = LOS does not meet the applicable jurisdictional requirements (i.e., unacceptable LOS).

N/A = Not Applicable; Segment does not exist.

[1] These maximum roadway capacities have been extracted from the City of Moreno Valley's Transportation Division's Traffic Impact Analysis Transportation Division's Traffic Impact Analysis Preparation Guidelines (August 2007). These roadway capacities are "rule of thumb" estimates for planning purposes. The LOS "E" service volumes are estimated maximum daily capacity for respective classifications. Capacity is affected by such factors as intersections (spacing, configuration and control features), degree of access control, roadway grades, design geometrics (horizontal and vertical alignment standards), sight distance, vehicle mix (truck and bus traffic) and pedestrian and bicycle traffic.

5.6 OFF-RAMP QUEUING ANALYSIS

Queuing analysis findings are presented in Table 5-3. As shown on Table 5-3, there are no queuing issues during the peak 95th percentile traffic flows under Existing Plus Project traffic conditions consistent with Existing traffic conditions. As such, the addition of Project traffic is not anticipated to result in any potential off-ramp queues at the SR-60 Freeway and Nason Street. Worksheets for Existing Plus Project traffic conditions off-ramp queuing analysis are provided in Appendix "5.3".

Table 5-3

Peak Hour Freeway Off-Ramp Queuing Summary for Existing Plus Project Conditions

Intersection	Movement	Available Stacking Distance (Feet)	95th Percentile Queue (Feet) [2]		Acceptable? [1]	
			AM Peak Hour	PM Peak Hour	AM	PM
Existing (2015) Conditions

	EBT	1,300	46	64	Yes	Yes
	EBR	225	45	62	Yes	Yes

[1] Stacking Distance is acceptable if the required stacking distance is less than or equal to the stacking distance provided. An additional 15 feet of stacking which is assumed to be provided in the transition for turn pockets is reflected in the stacking distance shown on this table, where applicable.
[2] Maximum queue length for the approach reported.

This Page Intentionally Left Blank

6 OPENING YEAR CUMULATIVE (2020) TRAFFIC ANALYSIS

This section discusses the methods used to develop Opening Year Cumulative Without and With Project traffic forecasts, and the resulting intersection operations, roadway segment analyses, and traffic signal warrants.

6.1 ROADWAY IMPROVEMENTS

The lane configurations and traffic controls assumed to be in place for Opening Year Cumulative conditions are consistent with those shown previously on Exhibit 3-1, with the exception of Project driveways assumed to be constructed by the Project to provide site access. In other words, no other off-site improvements are assumed beyond those that currently exist with the exception of the intersections and roadways that would be improved by the Project for access.

6.2 OPENING YEAR CUMULATIVE WITHOUT PROJECT TRAFFIC VOLUME FORECASTS

The weekday ADT, AM and PM peak hour volumes which can be expected for Opening Year Without Project traffic conditions are shown on Exhibit 6-1.

6.3 OPENING YEAR CUMULATIVE WITH PROJECT TRAFFIC VOLUME FORECASTS

The weekday ADT, AM and PM peak hour volumes which can be expected for Opening Year With Project traffic conditions are shown on Exhibit 6-2.

6.4 INTERSECTION OPERATIONS ANALYSIS

As shown in Table 6-1, all the study area intersections are anticipated to operate at acceptable LOS under both Opening Year Cumulative Without and With Project traffic conditions.

A summary of the peak hour intersection LOS for Opening Year Cumulative Without and With Project conditions are shown on Exhibits 6-3 and 6-4. The intersection operations analysis worksheets for Opening Year Cumulative Without and With Project traffic conditions are included in Appendix "6.1" and Appendix "6.2" of this TIA, respectively.

6.5 ROADWAY SEGMENT CAPACITY ANALYSIS

Table 6-2 provides a summary of the Opening Year Cumulative conditions roadway segment capacity analysis based on the City of Moreno Valley General Plan Circulation Element Roadway Segment Capacity/LOS Thresholds identified previously on Table 2-3. As shown on Table 6-2, all the study roadway segments are anticipated to operate at acceptable LOS with the exception of the segment of Ironwood Avenue, west of Nason Street.

10	Oliver Street	Between Street "C" and Ironwood Avenue	**2U**	2,000	N/A			517	0.26	A	C

BOLD = LOS does not meet the applicable jurisdictional requirements (i.e., unacceptable LOS).

N/A = Not Applicable; Segment does not exist.

[1] These maximum roadway capacities have been extracted from the City of Moreno Valley's Transportation Division's Traffic Impact Analysis Transportation Division's Traffic Impact Analysis Preparation Guidelines (August 2007). These roadway capacities are "rule of thumb" estimates for planning purposes. The LOS "E" service volumes are estimated maximum daily capacity for respective classifications. Capacity is affected by such factors as intersections (spacing, configuration and control features), degree of access control, roadway grades, design geometrics (horizontal and vertical alignment standards), sight distance, vehicle mix (truck and bus traffic) and pedestrian and bicycle traffic.

As noted previously in Section 2.3, where the ADT-based roadway segment analysis indicates a deficiency (unacceptable LOS), a review of the more detailed peak hour intersection analysis and progression analysis are undertaken. The more detailed peak hour intersection analysis explicitly accounts for factors that affect roadway capacity. Therefore, roadway segment widening is typically only recommended if the peak hour intersection analysis indicates the need for additional through lanes. The adjacent intersection of Nason Street at Ironwood Avenue is anticipated to operate at acceptable LOS under Opening Year Cumulative traffic conditions without roadway widening. As such, roadway widening or additional improvements to the eastbound approach at the intersection have not been recommended and are considered less-than-significant.

6.6 TRAFFIC SIGNAL WARRANTS ANALYSIS

Traffic signal warrants for Opening Year Cumulative traffic conditions are based on both Opening Year Cumulative Caltrans planning-level ADT and peak hour volumes. For Opening Year Cumulative Without and With Project conditions, there are no study intersections anticipated to meet traffic signal warrants (see Appendix “6.3” and Appendix “6.4”).

6.7 OFF-RAMP QUEUING ANALYSIS

Queuing analysis findings are presented in Table 6-3. As shown on Table 6-3, there are no queuing issues during the peak 95th percentile traffic flows under Opening Year Cumulative (2020) With and Without Project traffic conditions. Worksheets for Opening Year Cumulative (2020) With and Without Project traffic conditions off-ramp queuing analysis are provided in Appendix “6.5” and Appendix “6.6”, respectively.

Table 6-3

Peak Hour Freeway Off-Ramp Queuing Summary for Opening Year Cumulative (2020) Conditions

Intersection	Movement	Available Stacking Distance (Feet)	95th Percentile Queue (Feet) [2]		Acceptable? [1]	
			AM Peak Hour	PM Peak Hour	AM	PM
Opening Year Cumulative (2020) Without Project						
Nason St. / SR-60 WB Ramps	WBL	1,370	103	254 [3]	Yes	Yes
	WBT	2,140	22	33	Yes	Yes
	WBR	190	2	19	Yes	Yes
Nason St. / SR-60 EB Ramps	EBL	805	30	67	Yes	Yes
	EBT	1,300	98	45	Yes	Yes
	EBR	225	97	43	Yes	Yes
Opening Year Cumulative (2020) With Project						
Nason St. / SR-60 WB Ramps	WBL	1,370	106	254 [3]	Yes	Yes
	WBT	2,140	22	33	Yes	Yes
	WBR	190	4	25	Yes	Yes
Nason St. / SR-60 EB Ramps	EBL	805	37	129	Yes	Yes
	EBT	1,300	120	137	Yes	Yes
	EBR	225	118	134	Yes	Yes

[1] Stacking Distance is acceptable if the required stacking distance is less than or equal to the stacking distance provided. An additional 15 feet of stacking which is assumed to be provided in the transition for turn pockets is reflected in the stacking distance shown on this table, where applicable.

[2] Maximum queue length for the approach reported.

[3] 95th percentile volume exceeds capacity, queue may be longer. Queue shown is maximum after two cycles.

This Page Intentionally Left Blank

7 HORIZON YEAR (2035) TRAFFIC ANALYSIS

This section discusses the methods used to develop Horizon Year Without and With Project traffic forecasts, and the resulting intersection operations, roadway segment analyses, and traffic signal warrants.

7.1 ROADWAY IMPROVEMENTS

The lane configurations and traffic controls assumed to be in place for Horizon Year conditions are consistent with those shown previously on Exhibit 3-1, with the exception of Project driveways assumed to be constructed by the Project to provide site access. In other words, no other off-site improvements are assumed beyond those that currently exist with the exception of the intersections and roadways that would be improved by the Project for access.

7.2 HORIZON YEAR WITHOUT PROJECT TRAFFIC VOLUME FORECASTS

The weekday ADT, AM and PM peak hour volumes which can be expected for Horizon Year Without Project traffic conditions are shown on Exhibit 7-1.

7.3 OPENING YEAR CUMULATIVE WITH PROJECT TRAFFIC VOLUME FORECASTS

The weekday ADT, AM and PM peak hour volumes which can be expected for Horizon Year With Project traffic conditions are shown on Exhibit 7-2.

7.4 INTERSECTION OPERATIONS ANALYSIS

As shown in Table 7-1, all the study area intersections are anticipated to operate at acceptable LOS under both Horizon Year Without and With Project traffic conditions, with the exception of the intersection of Nason Street at Ironwood Avenue.

A summary of the peak hour intersection LOS for Horizon Year Without and With Project conditions are shown on Exhibits 7-3 and 7-4, respectively. The intersection operations analysis worksheets for Horizon Year Without and With Project traffic conditions are included in Appendix “7.1” and Appendix “7.2” of this TIA, respectively.

7.5 ROADWAY SEGMENT CAPACITY ANALYSIS

Table 7-2 provides a summary of the Horizon Year conditions roadway segment capacity analysis based on the City of Moreno Valley General Plan Circulation Element Roadway Segment Capacity/LOS Thresholds identified previously on Table 2-3. As shown on Table 7-2, all the study roadway segments are anticipated to operate at acceptable LOS with the exception of the segment of Ironwood Avenue, west of Nason Street.

10	Oliver Street	Between Street "C" and Ironwood Avenue	**2U**	2,000	N/A			517	0.26	A	C

BOLD = LOS does not meet the applicable jurisdictional requirements (i.e., unacceptable LOS).

N/A = Not Applicable; Segment does not exist.

[1] These maximum roadway capacities have been extracted from the City of Moreno Valley's Transportation Division's Traffic Impact Analysis Transportation Division's Traffic Impact Analysis Preparation Guidelines (August 2007). These roadway capacities are "rule of thumb" estimates for planning purposes. The LOS "E" service volumes are estimated maximum daily capacity for respective classifications. Capacity is affected by such factors as intersections (spacing, configuration and control features), degree of access control, roadway grades, design geometrics (horizontal and vertical alignment standards), sight distance, vehicle mix (truck and bus traffic) and pedestrian and bicycle traffic.

As noted previously in Section 2.3, where the ADT-based roadway segment analysis indicates a deficiency (unacceptable LOS), a review of the more detailed peak hour intersection analysis and progression analysis are undertaken. The more detailed peak hour intersection analysis explicitly accounts for factors that affect roadway capacity. Therefore, roadway segment widening is typically only recommended if the peak hour intersection analysis indicates the need for additional through lanes. The adjacent intersection of Nason Street at Ironwood Avenue is anticipated to operate at acceptable LOS under Horizon Year traffic conditions with turn lane improvements as identified on Table 6-4, but without additional through lanes. As such, roadway widening or additional improvements to the eastbound approach at the intersection have not been recommended beyond those needed to address peak hour intersection operational deficiencies and are considered less-than-significant.

7.6 TRAFFIC SIGNAL WARRANTS ANALYSIS

Traffic signal warrants for Horizon Year traffic conditions are based on both Horizon Year Caltrans planning-level ADT and peak hour volumes. For Horizon Year Without and With Project conditions, there are no study intersections anticipated to meet traffic signal warrants (see Appendix "7.3" and Appendix "7.4").

7.7 OFF-RAMP QUEUING ANALYSIS

Queuing analysis findings are presented in Table 7-3. As shown on Table 7-3, there are no queuing issues during the peak 95th percentile traffic flows under Horizon Year (2035) Without and With Project traffic conditions. Worksheets for Horizon Year (2035) Without and With Project traffic conditions off-ramp queuing analysis are provided in Appendix "7.5" and Appendix "7.6", respectively.

7.8 RECOMMENDED IMPROVEMENTS

Improvement strategies have been recommended at intersections that have been identified as deficient in an effort to reduce each location's peak hour delay and improve the associated LOS grade to an acceptable LOS (LOS D or better). The effectiveness of the recommended improvement strategies discussed below to address Horizon Year traffic deficiencies is presented in Table 7-4.

The applicant shall participate in the funding of off-site improvements, including traffic signals that are needed to serve cumulative traffic conditions through the payment of TUMF and City of Moreno Valley DIF fees (if the improvements are included in the TUMF or DIF programs) or on a fair share basis (if the improvements are not included in the TUMF or DIF programs). These fees shall be collected by the City of Moreno Valley, with the proceeds solely used as part of a funding mechanism aimed at ensuring that regional highways and arterial expansions keep pace with the projected population increases. There are no other applicable pre-existing funding programs for the study area aside from TUMF and DIF.

Worksheets for Horizon Year Without and With Project conditions, with improvements, HCM calculation worksheets are provided in Appendix "7.7" and Appendix "7.8," respectively.

Table 7-3

Peak Hour Freeway Off-Ramp Queuing Summary for Horizon Year (2035) Conditions

Intersection	Movement	Available Stacking Distance (Feet)	95th Percentile Queue (Feet) [2]		Acceptable? [1]	
			AM Peak Hour	PM Peak Hour	AM	PM
Horizon Year (2035) Without Project						
Nason St. / SR-60 WB Ramps	WBL	1,370	94	308 [3]	Yes	Yes
	WBT	2,140	16	62	Yes	Yes

URBAN CROSSROADS

41 Corporate Park | Suite 300 | Irvine, CA 92606 | (949) 660-1994
www.urbanXroads.com

Date: January 20, 2015
February 5, 2015 (Revised)

This letter acknowledges the City of Moreno Valley Transportation Engineering Division requirements for the traffic impact analysis of the following project:

Case No.	P14-130	
Project Name:	Ironwood Residential	
Project Address:	North of Ironwood Avenue, between Nason Street and Oliver Street	
Project Description:	144 single family residential dwelling units	
Related Cases:		
	Consultant	Developer Representative
Name:	URBAN CROSSROADS, INC. Attn: Aric Evatt	GLOBAL INVESTMENT & DEVELOPMENT, LLC Attn: Mr. Joseph Rivani
Address:	41 Corporate Park, Suite 300 Irvine, CA 92606	3470 Wilshire Blvd., Suite 1020 Los Angeles, CA 90010
Telephone:	949-660-1994 x. 204	213-369-9600

I. Background

The proposed Ironwood Residential development (referred to as "Project") is located north of Ironwood Avenue, east of Nason Street, and west of Oliver Street. The Project is proposed to consist of 144 single family, detached residential dwelling units. The Project is anticipated to be built in a single phase with an anticipated opening year of 2020 (minimum five-year opening year per Moreno Valley traffic study guidelines). See preliminary tentative tract map on **Exhibit 1**. **Exhibit 2** illustrates the study area and proposed existing and opening year intersection analysis locations.

II. Trip Geographic Distribution and Assignment

The project trip distribution patterns were developed based on an understanding of existing travel patterns in the area, the geographical location of the site, and the site's proximity to the regional arterial and state highway system (see **Exhibit 3**).

III. Site Trip Generation Forecast

A. Source for trip generation rates: Institute of Transportation Engineers (ITE) *Trip Generation Manual* 9th Edition (2012) for ITE Land Use Code 210 (Single Family Detached Residential).

B. Weekday AM Peak: 7:00-9:00 AM
C. Weekday PM Peak: 4:00-6:00 PM
D. Intersection and link acceptable Level of Service "D" for some intersections and links and Level of Service "C" for others based upon the current City policy. (Use Highway Capacity Manual 2010 operations procedures; parameters per County of Riverside Traffic Impact Analysis Guidelines)

Proposed Use Rates [(1)]

Single Family Residential

(per DU) Daily: 9.52 AM: 0.75 PM: 1.00

(See attached **Table 1**)

Internal Trip Allowance: Yes: ______ No: X Percentage: ______

Pass-by Trip Allowance: Yes: ______ No: X Percentage: ______

(1) Institute of Transportation Engineers 9th Edition *Trip Generation Manual* (2012).

IV. Specific Project Issues to be Analyzed

A. The traffic study will address the adequacy of site access and identify specific near-term circulation improvements required at study area intersections and roadways to maintain acceptable peak hour and daily levels of service (LOS).
B. The traffic study shall address the project traffic impacts at all study intersections listed in Section VI and provide appropriate mitigation measures if applicable. Peak-hour traffic signal warrants shall be evaluated for all intersections that are not currently signalized.
C. Qualitative assessment of existing and planned non-motorized facilities (e.g., pedestrians, bike routes, trails, etc.) within the study area.
D. The turn pocket lengths will be determined through peak hour traffic simulations developed using SimTraffic software in an effort to identify the required storage capacity for turn lanes at each Project driveway.
E. Provide a conceptual striping plan for the intersection of Nason Street and Ironwood Avenue for the traffic signal modification.
F. Recommend potential traffic calming measures for internal tract streets.

V. Study Horizon Year

A. Existing (2015)
B. Existing (2015) Plus Project
C. Opening Year Cumulative (2020) Without Project (existing to opening year-2020, assuming a growth rate of 2% per year and includes the traffic from other cumulative development projects in the vicinity)
D. Opening Year Cumulative (2020) With Project

VI. Facilities to be Studied

A. Analysis Locations: (See **Exhibit 2**)
1. Nason Street / Street "A" – Future Intersection
2. Nason Street / Ironwood Avenue
3. Nason Street / Elder Avenue/SR-60 Westbound Ramps
4. Nason Street / SR-60 Eastbound Ramps

5. Street "B"/Lantz Lane / Ironwood Avenue
6. Oliver Street / Street "C" – Future Intersection
7. Oliver Street / Ironwood Avenue

B. Roadway Segments:
All roadway segments adjacent to intersection analysis locations will be analyzed (e.g. all legs of intersections listed above).

VII. **Open Items**

A. **Cumulative Development Projects:** It is requested that the list of cumulative development projects be provided by the City for inclusion in the traffic study.

VIII. **Deliverables**

a. Draft traffic impact studies (2 copies each)
b. Final traffic impact studies (4 copies each)

All draft and final traffic impact studies shall be delivered with the appropriate review fee to the Permit Technician, Land Development Division - Moreno Valley City Hall, 14177 Frederick Street, Moreno Valley, CA 92552. Please contact the Land Development Division at 951-413-3110 prior to the delivery of the traffic study.

A review fee will be required upon submittal of the traffic study. **A signed copy of this *Scoping Agreement* must be included in the submitted draft and final traffic impact studies.**

If you have any questions regarding this *Scoping Agreement*, please contact Eric Lewis at 951-413-3140.

Recommended By:

Aric Evatt, PTP
Principal
Urban Crossroads, Inc.

Approved By:

Eric Lewis, City of Moreno Valley

TRAFFIC CONDITIONS **E+P**

DIST ___ CO ___ RTE ___ PM ___

CALC CHS DATE 08/25/15

CHK CHS DATE 08/25/15

Jurisdiction: **City of Moreno Valley**

Major Street: **Nason Street**

Minor Street: **Street "A"**

Critical Approach Speed (Major) 25 mph

Critical Approach Speed (Minor) 25 mph

Major Street Approach Lanes = **1** lane

Minor Street Approach Lanes **1** lane

Major Street Future ADT = **379** vpd

Minor Street Future ADT = **259** vpd

Speed limit or critical speed on major street traffic > 64 km/h (40 mph); ……….. ☐

or **URBAN (U)**

In built up area of isolated community of < 10,000 population …………………… ☐

(Based on Estimated Average Daily Traffic - See Note)

URBAN XX	RURAL	Minimum Requirements EADT			
CONDITION A - Minimum Vehicular Volume		Vehicles Per Day on Major Street (Total of Both Approaches)		Vehicles Per Day on Higher-Volume Minor Street Approach (One Direction Only)	
Satisfied	Not Satisfied XX				
Number of lanes for moving traffic on each approach					
Major Street	Minor Street	Urban	Rural	Urban	Rural
1 **379**	1 **259**	8,000	5,600	2,400	1,680
2 +	1	9,600	6,720	2,400	1,680
2 +	2 +	9,600	6,720	3,200	2,240
1	2 +	8,000	5,600	3,200	2,240
CONDITION B - Interruption of Continuous Traffic		Vehicles Per Day on Major Street (Total of Both Approaches)		Vehicles Per Day on Higher-Volume Minor Street Approach (One Direction Only)	
Satisfied	Not Satisfied XX				
Number of lanes for moving traffic on each approach					
Major Street	Minor Street	Urban	Rural	Urban	Rural
1 **379**	1 **259**	12,000	8,400	1,200	850
2 +	1	14,400	10,080	1,200	850
2 +	2 +	14,400	10,080	1,600	1,120
1	2 +	12,000	8,400	1,600	1,120
Combination of CONDITIONS A + B		2 CONDITIONS 80%		2 CONDITIONS 80%	
Satisfied	Not Satisfied XX				
No one condition satisfied, but following conditions fulfilled 80% of more …..	A **5%** / B **3%**				

Note: To be used only for NEW INTERSECTIONS or other locations where it is not reasonable to count actual traffic volumes.

The satisfaction of a traffic signal warrant or warrants shall not in itself require the installation of a traffic control signal.

URBAN CROSSROADS

Figure 4C-4. Warrant 3, Peak Hour (70% Factor)

(COMMUNITY LESS THAN 10,000 POPULATION OR ABOVE 64 km/h OR ABOVE 40 mph ON MAJOR STREET)

Traffic Conditions = **E+P Conditions - Weekday AM Peak Hour**

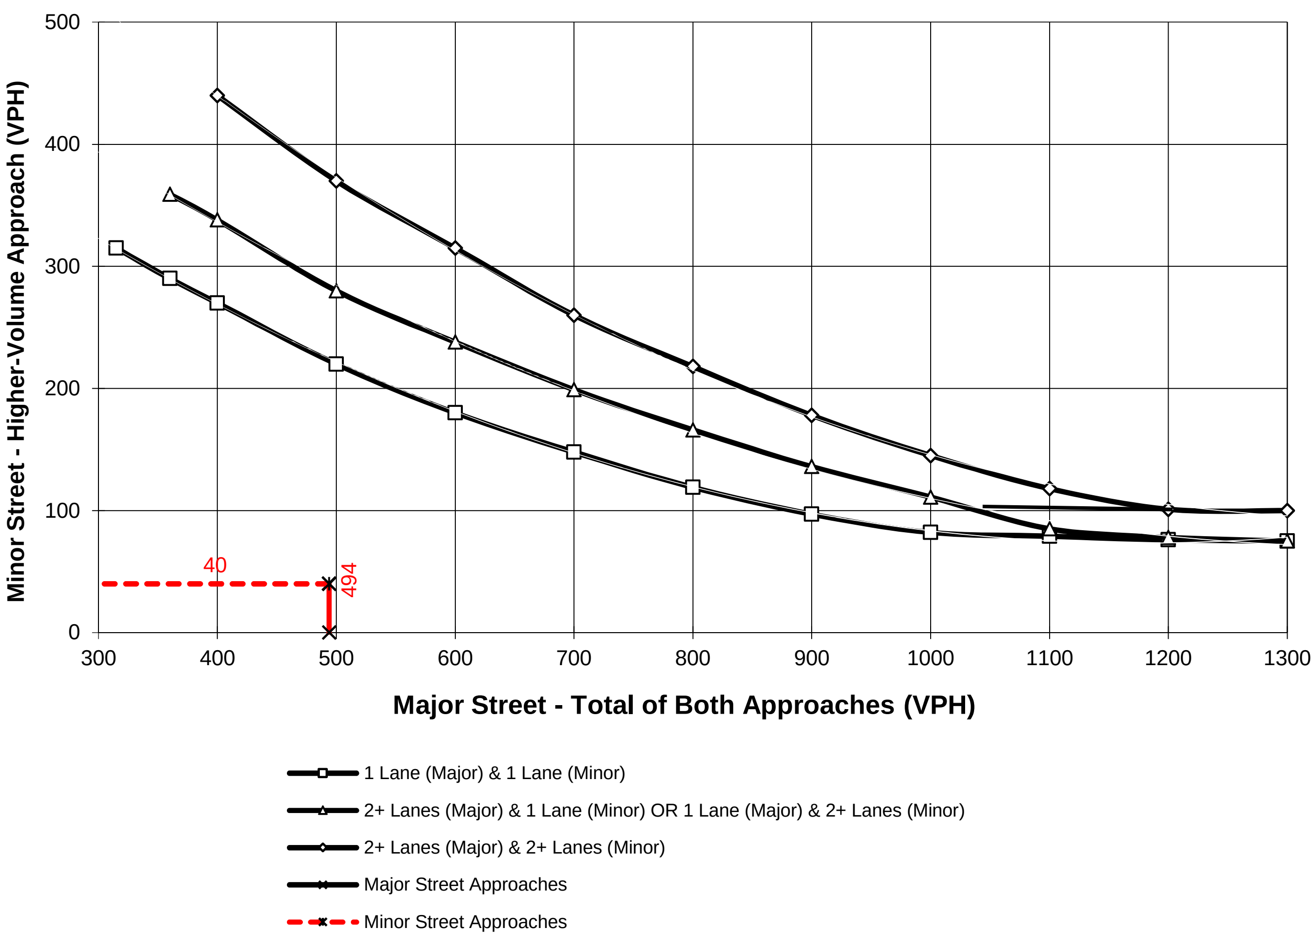
Major Street Name = **Ironwood Avenue**

Total of Both Approaches (VPH) = **494**
Number of Approach Lanes Major Street = **1**

Minor Street Name = **Lantz Lane**

High Volume Approach (VPH) = **40**
Number of Approach Lanes Minor Street = **1**

SIGNAL WARRANT NOT SATISFIED



*Note: 100 vph applies as the lower threshold for a minor-street approach with two or more lanes and 75 vph applies as the lower threshold for a minor-street approach with one lane

(Average Traffic Estimate Form)

TRAFFIC CONDITIONS **2020 WP**

DIST	CO	RTE	PM	CALC	CHS	DATE	08/25/15
				CHK	CHS	DATE	08/25/15

Jurisdiction: **City of Moreno Valley**
Major Street: **Oliver Street**
Minor Street: **Street "C"**

Critical Approach Speed (Major) 25 mph
Critical Approach Speed (Minor) 25 mph

Major Street Approach Lanes = **1** lane
Minor Street Approach Lanes **1** lane

Major Street Future ADT = **259** vpd
Minor Street Future ADT = **259** vpd

Speed limit or critical speed on major street traffic > 64 km/h (40 mph); ……….. ☐

or **URBAN (U)**

In built up area of isolated community of < 10,000 population …………………… ☐

(Based on Estimated Average Daily Traffic - See Note)

URBAN	RURAL	Minimum Requirements EADT			
XX					
CONDITION A - Minimum Vehicular Volume		Vehicles Per Day on Major Street (Total of Both Approaches)		Vehicles Per Day on Higher-Volume Minor Street Approach (One Direction Only)	
Satisfied	Not Satisfied				
	XX				
Number of lanes for moving traffic on each approach					
Major Street	Minor Street	Urban	Rural	Urban	Rural
1 **259**	1 **259**	8,000	5,600	2,400	1,680
2 +	1	9,600	6,720	2,400	1,680
2 +	2 +	9,600	6,720	3,200	2,240
1	2 +	8,000	5,600	3,200	2,240
CONDITION B - Interruption of Continuous Traffic		Vehicles Per Day on Major Street (Total of Both Approaches)		Vehicles Per Day on Higher-Volume Minor Street Approach (One Direction Only)	
Satisfied	Not Satisfied				
	XX				
Number of lanes for moving traffic on each approach					
Major Street	Minor Street	Urban	Rural	Urban	Rural
1 **259**	1 **259**	12,000	8,400	1,200	850
2 +	1	14,400	10,080	1,200	850
2 +	2 +	14,400	10,080	1,600	1,120
1	2 +	12,000	8,400	1,600	1,120
Combination of CONDITIONS A + B		2 CONDITIONS 80%		2 CONDITIONS 80%	
Satisfied	Not Satisfied				
	XX				
No one condition satisfied, but following conditions fulfilled 80% of more …..	A: 3% B: 2%				

Note: To be used only for NEW INTERSECTIONS or other locations where it is not reasonable to count actual traffic volumes.

The satisfaction of a traffic signal warrant or warrants shall not in itself require the installation of a traffic control signal.

Figure 4C-4. Warrant 3, Peak Hour (70% Factor)

(COMMUNITY LESS THAN 10,000 POPULATION OR ABOVE 64 km/h OR ABOVE 40 mph ON MAJOR STREET)

Traffic Conditions = **Opening Year (2020) Cumulative With Project Conditions - Weekday AM Peak Hour**

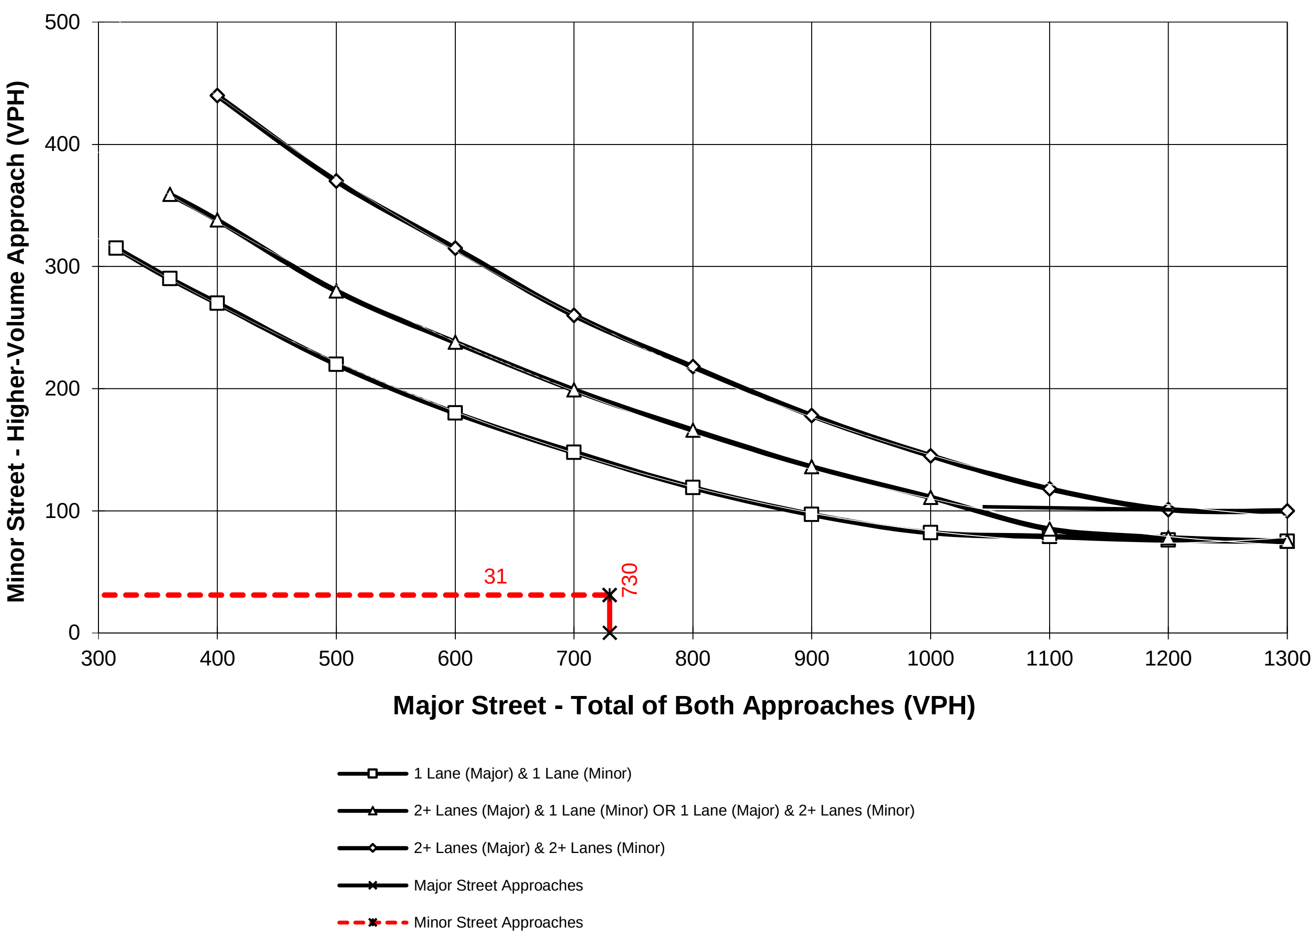
Major Street Name = **Ironwood Avenue**

Total of Both Approaches (VPH) = **730**
Number of Approach Lanes Major Street = **1**

Minor Street Name = **Oliver Street**

High Volume Approach (VPH) = **31**
Number of Approach Lanes Minor Street = **1**

SIGNAL WARRANT NOT SATISFIED



*Note: 100 vph applies as the lower threshold for a minor-street approach with two or more lanes and 75 vph applies as the lower threshold for a minor-street approach with one lane

Major Street Name = **Ironwood Avenue**

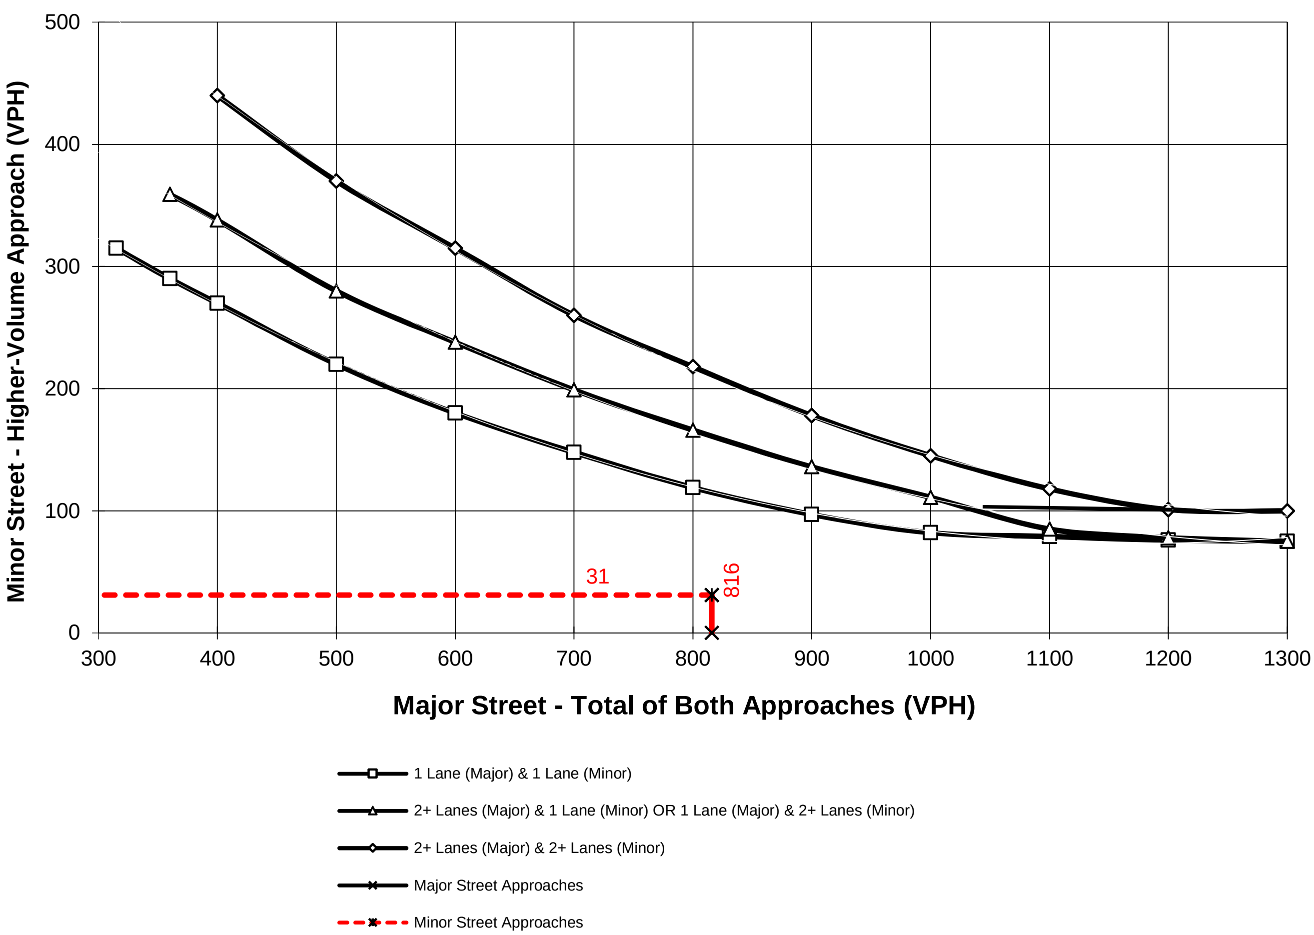
Total of Both Approaches (VPH) = **816**
Number of Approach Lanes Major Street = **1**

Minor Street Name = **Oliver Street**

High Volume Approach (VPH) = **31**
Number of Approach Lanes Minor Street = **1**

SIGNAL WARRANT NOT SATISFIED



*Note: 100 vph applies as the lower threshold for a minor-street approach with two or more lanes and 75 vph applies as the lower threshold for a minor-street approach with one lane

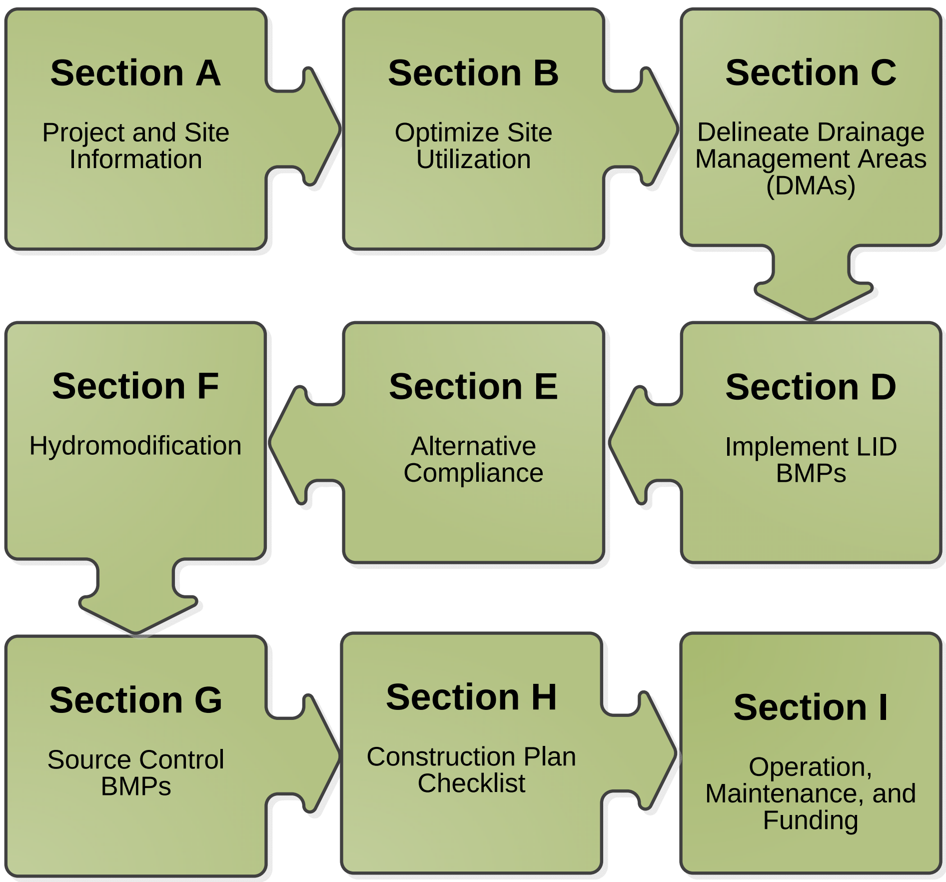
A Brief Introduction

This Project-Specific WQMP Template for the **Santa Ana Region** has been prepared to help guide you in documenting compliance for your project. Because this document has been designed to specifically document compliance, you will need to utilize the WQMP Guidance Document as your "how-to" manual to help guide you through this process. Both the Template and Guidance Document go hand-in-hand, and will help facilitate a well prepared Project-Specific WQMP. Below is a flowchart for the layout of this Template that will provide the steps required to document compliance.



OWNER'S CERTIFICATION

This Project-Specific Water Quality Management Plan (WQMP) has been prepared for Global Investment by JLC Engineering and Consulting, Inc. for the Ironwood Project, Tentative Tract Map 37001.

This WQMP is intended to comply with the requirements of the City of Moreno Valley for Ordinance No. 827 which includes the requirement for the preparation and implementation of a Project-Specific WQMP.

The undersigned, while owning the property/project described in the preceding paragraph, shall be responsible for the implementation and funding of this WQMP and will ensure that this WQMP is amended as appropriate to reflect up-to-date conditions on the site. In addition, the property owner accepts responsibility for interim operation and maintenance of Stormwater BMPs until such time as this responsibility is formally transferred to a subsequent owner. This WQMP will be reviewed with the facility operator, facility supervisors, employees, tenants, maintenance and service contractors, or any other party (or parties) having responsibility for implementing portions of this WQMP. At least one copy of this WQMP will be maintained at the project site or project office in perpetuity. The undersigned is authorized to certify and to approve implementation of this WQMP. The undersigned is aware that implementation of this WQMP is enforceable under the City of Moreno Valley Water Quality Ordinance 827.

"I, the undersigned, certify under penalty of law that the provisions of this WQMP have been reviewed and accepted and that the WQMP will be transferred to future successors in interest."

Owner's Signature	Date
Owner's Printed Name	Owner's Title/Position

PREPARER'S CERTIFICATION

"The selection, sizing and design of stormwater treatment and other stormwater quality and quantity control measures in this plan meet the requirements of Regional Water Quality Control Board Order No. **R8-2010-0033** and any subsequent amendments thereto."

	September 29, 2015

List of Appendices

Section A: Project and Site Information

PROJECT INFORMATION		
Type of Project:	Residential	
Planning Area:	N/A	
Community Name:	City Of Moreno Valley	
Development Name:	Ironwood – TTM 37001	
PROJECT LOCATION		
Latitude & Longitude (DMS): 33°56'52"N 117°11'13"W		
Project Watershed and Sub-Watershed: Santa Ana River Watershed, San Jacinto River Sub-Watershed		
APN(s): Portions of 473-160-004		
Map Book and Page No.: Book 473, page 160		
PROJECT CHARACTERISTICS		
Proposed or Potential Land Use(s)		Residential
Proposed or Potential SIC Code(s)		N/A
Area of Impervious Project Footprint (SF)		1,470,368
Total Area of <u>proposed</u> Impervious Surfaces within the Project Limits (SF)/or Replacement		1,470,368
Does the project consist of offsite road improvements?		☒ Y ☐ N
Does the project propose to construct unpaved roads?		☐ Y ☒ N
Is the project part of a larger common plan of development (phased project)?		☐ Y ☒ N
EXISTING SITE CHARACTERISTICS		
Total area of <u>existing</u> Impervious Surfaces within the project limits (SF)		0
Is the project located within any MSHCP Criteria Cell?		☐ Y ☒ N
If so, identify the Cell number:		N/A
Are there any natural hydrologic features on the project site?		☐ Y ☒ N
Is a Geotechnical Report attached?		☒ Y ☐ N
If no Geotech. Report, list the NRCS soils type(s) present on the site (A, B, C and/or D)		Hydrologic Soil "A", "C" and "D"
What is the Water Quality Design Storm Depth for the project?		0.70

A.1 Maps and Site Plans

When completing your Project-Specific WQMP, include a map of the local vicinity and existing site. In addition, include all grading, drainage, landscape/plant palette and other pertinent construction plans in Appendix 2. At a **minimum**, your WQMP Site Plan should include the following:

- Drainage Management Areas
- Proposed Structural BMPs
- Drainage Path
- Drainage Infrastructure, Inlets, Overflows
- Source Control BMPs
- Buildings, Roof Lines, Downspouts
- Impervious Surfaces
- Standard Labeling

Use your discretion on whether or not you may need to create multiple sheets or can appropriately accommodate these features on one or two sheets. Keep in mind that the Co-Permittee plan reviewer must be able to easily analyze your project utilizing this template and its associated site plans and maps.

A.2 Identify Receiving Waters

Using Table A.1 below, list in order of upstream to downstream, the receiving waters that the project site is tributary to. Continue to fill each row with the Receiving Water's 303(d) listed impairments (if any), designated beneficial uses, and proximity, if any, to a RARE beneficial use. Include a map of the receiving waters in Appendix 1.

Table A.1 Identification of Receiving Waters

Receiving Waters	EPA Approved 303(d) List Impairments	Designated Beneficial Uses	Proximity to RARE Beneficial Use
Natural Stream	N/A	N/A	Not a RARE-designated water body
Nason Basin	N/A	N/A	N/A
Moreno MDP Line I Storm Drain	N/A	N/A	N/A
Moreno ADP Line F Storm Drain	N/A	N/A	N/A
Kitching Street Channel – Line N	N/A	N/A	Not a RARE-designated water body
Perris Valley Channel	N/A	N/A	Not a RARE-designated water body
San Jacinto River	N/A	MUN, AGR, GWR, REC1, REC2, WARM, WILD	Not a RARE-designated water body
Canyon Lake	Nutrients, Pathogens (Bacteria & Viruses)	MUN, AGR, GWR, REC1, REC2, WAR, WILD	Not a RARE-designated water body
San Jacinto River	N/A	MUN, AGR, GWR, REC1, REC2, WARM, WILD	Not a RARE-designated water body
Lake Elsinore	Metals (Mercury), Nutrients, Organic Enrichment/Low Dissolved Oxygen, Polychlorinated biphenyls, sediment Toxicity, Sedimentation, Unknown Toxicity	REC1, REC2, WARM, WILD	Not a RARE-designated water body

A.3 Additional Permits/Approvals required for the Project:

Table A.2 Other Applicable Permits

Agency	Permit Required	
State Department of Fish and Game, 1602 Streambed Alteration Agreement	☐ Y	☒ N
State Water Resources Control Board, Clean Water Act (CWA) Section 401 Water Quality Cert.	☐ Y	☒ N
US Army Corps of Engineers, CWA Section 404 Permit	☐ Y	☒ N
US Fish and Wildlife, Endangered Species Act Section 7 Biological Opinion	☐ Y	☒ N
Statewide Construction General Permit Coverage	☒ Y	☐ N
Statewide Industrial General Permit Coverage	☐ Y	☒ N
Western Riverside MSHCP Consistency Approval (e.g., JPR, DBESP)	☐ Y	☒ N
Other *(please list in the space below as required)*	☐ Y	☐ N

If yes is answered to any of the questions above, the Co-Permittee may require proof of approval/coverage from those agencies as applicable including documentation of any associated requirements that may affect this Project-Specific WQMP.

Section B: Optimize Site Utilization (LID Principles)

Review of the information collected in Section 'A' will aid in identifying the principal constraints on site design and selection of LID BMPs as well as opportunities to reduce imperviousness and incorporate LID Principles into the site and landscape design. For example, constraints might include impermeable soils, high groundwater, groundwater pollution or contaminated soils, steep slopes, geotechnical instability, high-intensity land use, heavy pedestrian or vehicular traffic, utility locations or safety concerns. Opportunities might include existing natural areas, low areas, oddly configured or otherwise unbuildable parcels, easements and landscape amenities including open space and buffers (which can double as locations for bioretention BMPs), and differences in elevation (which can provide hydraulic head). Prepare a brief narrative for each of the site optimization strategies described below. This narrative will help you as you proceed with your LID design and explain your design decisions to others.

The 2010 Santa Ana MS4 Permit further requires that LID Retention BMPs (Infiltration Only or Harvest and Use) be used unless it can be shown that those BMPs are infeasible. Therefore, it is important that your narrative identify and justify if there are any constraints that would prevent the use of those categories of LID BMPs. Similarly, you should also note opportunities that exist which will be utilized during project design. Upon completion of identifying Constraints and Opportunities, include these on your WQMP Site plan in Appendix 1.

Site Optimization

The following questions are based upon Section 3.2 of the WQMP Guidance Document. Review of the WQMP Guidance Document will help you determine how best to optimize your site and subsequently identify opportunities and/or constraints, and document compliance.

Did you identify and preserve existing drainage patterns? If so, how? If not, why?

The project site currently drains from the north and to the south into three existing culverts crossing Ironwood Avenue. The project will preserve these existing drainage patterns.

Did you identify and protect existing vegetation? If so, how? If not, why?

The project will preserve existing vegetation through the central portion of the project site, as well as a portion of the northerly project site.

Did you identify and preserve natural infiltration capacity? If so, how? If not, why?

The infiltration rates for the project site are low, with the highest rate being 0.82 in/hr. Open space areas are proposed within the project limits which will preserve natural infiltration capabilities, however, infiltration will not be utilized as a method of water quality treatment due to the low infiltration rates.

Did you identify and minimize impervious area? If so, how? If not, why?

The project site minimizes impervious areas, where feasible.

Did you identify and disperse runoff to adjacent pervious areas? If so, how? If not, why?

The project site will direct roof runoff through adjacent landscaping.

Section C: Delineate Drainage Management Areas (DMAs)

Utilizing the procedure in Section 3.3 of the WQMP Guidance Document which discusses the methods of delineating and mapping your project site into individual DMAs, complete Table C.1 below to appropriately categorize the types of classification (e.g., Type A, Type B, etc.) per DMA for your project site. Upon completion of this table, this information will then be used to populate and tabulate the corresponding tables for their respective DMA classifications.

Table C.1 DMA Classifications

DMA Name or ID	Surface Type(s)[1]	Area (Sq. Ft.)	DMA Type
DMA A	Roof, Landscaping, Street, Natural Soil D	2,128,777	Type “D”
DMA B	Roof, Landscaping, Street, Natural Soil D	4,864,781	Type “D”

[1]*Reference Table 2-1 in the WQMP Guidance Document to populate this column*

Table C.2 Type ‘A’, Self-Treating Areas

DMA Name or ID	Area (Sq. Ft.)	Stabilization Type	Irrigation Type (if any)

Table C.3 Type ‘B’, Self-Retaining Areas

Self-Retaining Area				**Type ‘C’ DMAs that are draining to the Self-Retaining Area**		
DMA Name/ ID	Post-project surface type	Area (square feet) [A]	Storm Depth (inches) [B]	DMA Name / ID	[C] from Table C.4 = [C]	Required Retention Depth (inches) [D]

$$[D] = [B] + \frac{[B] \cdot [C]}{[A]}$$

Table C.4 Type 'C', Areas that Drain to Self-Retaining Areas

DMA					Receiving Self-Retaining DMA		
DMA Name/ ID	Area (square feet) [A]	Post-project surface type	Runoff factor [B]	Product [C] = [A] x [B]	DMA name /ID	Area (square feet) [D]	Ratio [C]/[D]

Table C.5 Type 'D', Areas Draining to BMPs

DMA Name or ID	BMP Name or ID
DMA A	Bioretention Basin A
DMA B	Bioretention Basin B

<u>Note</u>: More than one drainage management area can drain to a single LID BMP, however, one drainage management area may not drain to more than one BMP.

Section D: Implement LID BMPs

D.1 Infiltration Applicability

Is there an approved downstream 'Highest and Best Use' for stormwater runoff (see discussion in Chapter 2.4.4 of the WQMP Guidance Document for further details)? ☐ Y ☒ N

If yes has been checked, Infiltration BMPs shall not be used for the site. If no, continue working through this section to implement your LID BMPs. It is recommended that you contact your Co-Permittee to verify whether or not your project discharges to an approved downstream 'Highest and Best Use' feature.

Geotechnical Report

A Geotechnical Report or Phase I Environmental Site Assessment may be required by the Copermittee to confirm present and past site characteristics that may affect the use of Infiltration BMPs. In addition, the Co-Permittee, at their discretion, may not require a geotechnical report for small projects as described in Chapter 2 of the WQMP Guidance Document. If a geotechnical report has been prepared, include it in Appendix 3. In addition, if a Phase I Environmental Site Assessment has been prepared, include it in Appendix 4.

Is this project classified as a small project consistent with the requirements of Chapter 2 of the WQMP Guidance Document? ☐ Y ☒ N

Infiltration Feasibility

Table D.1 below is meant to provide a simple means of assessing which DMAs on your site support Infiltration BMPs and is discussed in the WQMP Guidance Document in Chapter 2.4.5. Check the appropriate box for each question and then list affected DMAs as applicable. If additional space is needed, add a row below the corresponding answer.

Table D.1 Infiltration Feasibility

Does the project site…	YES	NO
…have any DMAs with a seasonal high groundwater mark shallower than 10 feet?		X
If Yes, list affected DMAs:		
…have any DMAs located within 100 feet of a water supply well?		X
If Yes, list affected DMAs:		
…have any areas identified by the geotechnical report as posing a public safety risk where infiltration of stormwater could have a negative impact?		X
If Yes, list affected DMAs:		
…have measured in-situ infiltration rates of less than 1.6 inches / hour?	X	
If Yes, list affected DMAs: DMA A and DMA B		
…have significant cut and/or fill conditions that would preclude in-situ testing of infiltration rates at the final infiltration surface?		X
If Yes, list affected DMAs:		
…geotechnical report identify other site-specific factors that would preclude effective and safe infiltration?		X
Describe here:		

If you answered "Yes" to any of the questions above for any DMA, Infiltration BMPs should not be used for those DMAs and you should proceed to the assessment for Harvest and Use below.

DMA's A and B have low infiltration rates, specifically 0.45 in/hr, 0.50 in/hr, and 0.82 in/hr, which are significantly lower than the minimum 1.6 in/hr required to utilize infiltration as a water quality treatment mechanism. Therefore the project site did not utilize infiltration. The Preliminary Geotechnical Evaluation has been included in Appendix 3.

D.2 Harvest and Use Assessment

Please check what applies*:*

- ☐ Reclaimed water will be used for the non-potable water demands for the project.
- ☐ Downstream water rights may be impacted by Harvest and Use as approved by the Regional Board (verify with the Copermittee).
- ☐ The Design Capture Volume will be addressed using Infiltration Only BMPs. In such a case, Harvest and Use BMPs are still encouraged, but it would not be required if the Design Capture Volume will be infiltrated or evapotranspired.

If any of the above boxes have been checked, Harvest and Use BMPs need not be assessed for the site. If neither of the above criteria applies, follow the steps below to assess the feasibility of irrigation use, toilet use and other non-potable uses (e.g., industrial use).

Irrigation Use Feasibility

Complete the following steps to determine the feasibility of harvesting stormwater runoff for Irrigation Use BMPs on your site:

Step 1: Identify the total area of irrigated landscape on the site, and the type of landscaping used.

Total Area of Irrigated Landscape: 33.76

Type of Landscaping (Conservation Design or Active Turf): Conservation

Step 2: Identify the planned total of all impervious areas on the proposed project from which runoff might be feasibly captured and stored for irrigation use. Depending on the configuration of buildings and other impervious areas on the site, you may consider the site as a whole, or parts of the site, to evaluate reasonable scenarios for capturing and storing runoff and directing the stored runoff to the potential use(s) identified in Step 1 above.

Total Area of Impervious Surfaces: 33.76

Step 3: Cross reference the Design Storm depth for the project site (see Exhibit A of the WQMP Guidance Document) with the left column of Table 2-3 in Chapter 2 to determine the minimum area of Effective Irrigated Area per Tributary Impervious Area (EIATIA).

Enter your EIATIA factor: 1.32

Step 4: Multiply the unit value obtained from Step 3 by the total of impervious areas from Step 2 to develop the minimum irrigated area that would be required.

Minimum required irrigated area: 44.56

Step 5: Determine if harvesting stormwater runoff for irrigation use is feasible for the project by comparing the total area of irrigated landscape (Step 1) to the minimum required irrigated area (Step 4).

Minimum required irrigated area (Step 4)	Available Irrigated Landscape (Step 1)
44.56	33.76

Toilet Use Feasibility

Complete the following steps to determine the feasibility of harvesting stormwater runoff for toilet flushing uses on your site:

Step 1: Identify the projected total number of daily toilet users during the wet season, and account for any periodic shut downs or other lapses in occupancy:

Projected Number of Daily Toilet Users: 453

Project Type: Residential

Step 2: Identify the planned total of all impervious areas on the proposed project from which runoff might be feasibly captured and stored for toilet use. Depending on the configuration of buildings and other impervious areas on the site, you may consider the site as a whole, or parts of the site, to evaluate reasonable scenarios for capturing and storing runoff and directing the stored runoff to the potential use(s) identified in Step 1 above.

Total Area of Impervious Surfaces: 33.76

Step 3: Enter the Design Storm depth for the project site (see Exhibit A) into the left column of Table 2-1 in Chapter 2 to determine the minimum number or toilet users per tributary impervious acre (TUTIA).

Enter your TUTIA factor: 116

Step 4: Multiply the unit value obtained from Step 3 by the total of impervious areas from Step 2 to develop the minimum number of toilet users that would be required.

Minimum number of toilet users: 3,916

Step 5: Determine if harvesting stormwater runoff for toilet flushing use is feasible for the project by comparing the Number of Daily Toilet Users (Step 1) to the minimum required number of toilet users (Step 4).

Minimum required Toilet Users (Step 4)	Projected number of toilet users (Step 1)
3,916	453

Other Non-Potable Use Feasibility

Are there other non-potable uses for stormwater runoff on the site (e.g. industrial use)? See Chapter 2 of the Guidance for further information. If yes, describe below. If no, write N/A.

N/A

Step 1: Identify the projected average daily non-potable demand, in gallons per day, during the wet season and accounting for any periodic shut downs or other lapses in occupancy or operation.

Average Daily Demand: N/A

Step 2: Identify the planned total of all impervious areas on the proposed project from which runoff might be feasibly captured and stored for the identified non-potable use. Depending on the configuration of buildings and other impervious areas on the site, you may consider the site as a whole, or parts of the site, to evaluate reasonable scenarios for capturing and storing runoff and directing the stored runoff to the potential use(s) identified in Step 1 above.

Total Area of Impervious Surfaces: N/A

Step 3: Enter the Design Storm depth for the project site (see Exhibit A) into the left column of Table 2-3 in Chapter 2 to determine the minimum demand for non-potable uses per tributary impervious acre.

Enter the factor from Table 2-3: N/A

Step 4: Multiply the unit value obtained from Step 4 by the total of impervious areas from Step 3 to develop the minimum number of gallons per day of non-potable use that would be required.

Minimum required use: N/A

Step 5: Determine if harvesting stormwater runoff for other non-potable use is feasible for the project by comparing the Number of Daily Toilet Users (Step 1) to the minimum required number of toilet users (Step 4).

Minimum required non-potable use (Step 4)	**Projected average daily use (Step 1)**
N/A	N/A

If Irrigation, Toilet and Other Use feasibility anticipated demands are less than the applicable minimum values, Harvest and Use BMPs are not required and you should proceed to utilize LID Bioretention and Biotreatment, unless a site-specific analysis has been completed that demonstrates technical infeasibility as noted in D.3 below.

Based upon the Harvest and Use analysis, the project site does not have sufficient irrigated landscaped area or toilet users to utilize Harvest and Use BMPs.

Other LID Bioretention and Biotreatment BMPs as described in Chapter 2.4.7 of the WQMP Guidance Document are feasible on nearly all development sites with sufficient advance planning.

Select one of the following:

☒ LID Bioretention/Biotreatment BMPs will be used for some or all DMAs of the project as noted below in Section D.4 (note the requirements of Section 3.4.2 in the WQMP Guidance Document).

☐ A site-specific analysis demonstrating the technical infeasibility of all LID BMPs has been performed and is included in Appendix 5. If you plan to submit an analysis demonstrating the technical infeasibility of LID BMPs, request a pre-submittal meeting with the Copermittee to discuss this option. Proceed to Section E to document your alternative compliance measures.

D.3 Feasibility Assessment Summaries

From the Infiltration, Harvest and Use, Bioretention and Biotreatment Sections above, complete Table D.2 below to summarize which LID BMPs are technically feasible, and which are not, based upon the established hierarchy.

Table D.2 LID Prioritization Summary Matrix

DMA Name/ID	LID BMP Hierarchy				No LID (Alternative Compliance)
	1. Infiltration	2. Harvest and use	3. Bioretention	4. Biotreatment	
DMA A	☐	☐	☒	☐	☐
DMA B	☐	☐	☒	☐	☐
	☐	☐	☐	☐	☐
	☐	☐	☐	☐	☐
	☐	☐	☐	☐	☐
	☐	☐	☐	☐	☐

For those DMAs where LID BMPs are not feasible, provide a brief narrative below summarizing why they are not feasible, include your technical infeasibility criteria in Appendix 5, and proceed to Section E below to document Alternative Compliance measures for those DMAs. Recall that each proposed DMA must pass through the LID BMP hierarchy before alternative compliance measures may be considered.

The project site will utilize bioretention basins to treat for water quality purposes. The required water quality volume was determined by using the Santa Ana Watershed BMP Design Volume Spreadsheets. The effective impervious fraction was calculated using 50% impervious area for the onsite area, and natural soil type "D" for the offsite area. The following table summarizes the effective impervious fraction calculations:

Area "A"

Land Cover	Area (ac)	Effective Impervious Fraction
Residential – Impervious	11.2	1.0
Residential – Pervious	11.2	0.1
Natural Cover – Soil D	26.47	0.4
TOTAL	**48.87**	**0.47**

Area "B"

Land Cover	Area (ac)	Effective Impervious Fraction
Residential – Impervious	22.56	1.0
Residential – Pervious	22.55	0.1
Natural Cover – Soil D	66.57	0.4
TOTAL	**111.68**	**0.46**

The bioretention basins have been designed so that the water quality volume will not pond higher than 6" above the soil media using the Bioretention Basin Design Spreadsheets. The remaining volume will be utilized for meeting the hydrologic conditions of concern and mitigating for increased runoff.

The water quality volume calculations and effective impervious fraction calculations have been included in Appendix 6.

D.4 LID BMP Sizing

Each LID BMP must be designed to ensure that the Design Capture Volume will be addressed by the selected BMPs. First**,** calculate the Design Capture Volume for each LID BMP using the V_{BMP} worksheet in Appendix F of the LID BMP Design Handbook. Second**,** design the LID BMP to meet the required V_{BMP} using a method approved by the Copermittee. Utilize the worksheets found in the LID BMP Design Handbook or consult with your Copermittee to assist you in correctly sizing your LID BMPs. Complete Table D.3 below to document the Design Capture Volume and the Proposed Volume for each LID BMP. Provide the completed design procedure sheets for each LID BMP in Appendix 6. You may add additional rows to the table below as needed. **NOTE: Proposed volume is up to 0.5 feet of depth. Bioretention basins include storage within soil media and gravel layers.**

Table D.3 DCV Calculations for LID BMPs

DMA Type/ID	DMA Area (square feet)	Post-Project Surface Type	Effective Impervious Fraction, I_f	DMA Runoff Factor	DMA Areas x Runoff Factor	*Bioretention Basin A/DMA A*		
	[A]		[B]	[C]	[A] x [C]			
DMA A-1	*2128777.2*	*Mixed surface types*	*0.47*	*0.32*	*682396.8*	*Design Storm Depth (in)*	*Design Capture Volume,* V_{BMP} *(cubic feet)*	*Proposed Volume on Plans (cubic feet)*
	2128777.2				682396.8	0.70	39806.5	57912.8

[B], [C] is obtained as described in Section 2.3.1 of the WQMP Guidance Document
[E] is obtained from Exhibit A in the WQMP Guidance Document
[G] is obtained from a design procedure sheet, such as in LID BMP Design Handbook and placed in Appendix 6

Table D.4 DCV Calculations for LID BMPs

DMA Type/ID	DMA Area (square feet)	Post-Project Surface Type	Effective Impervious Fraction, I_f	DMA Runoff Factor	DMA Areas x Runoff Factor	*Bioretention Basin B/DMA B*		
	[A]		[B]	[C]	[A] x [C]			
DMA B-1	*4864780.8*	*Mixed surface types*	*0.46*	*0.31*	*1530004.2*	*Design Storm Depth (in)*	*Design Capture Volume,* V_{BMP} *(cubic feet)*	*Proposed Volume on Plans (cubic feet)*
	4864780.8				1530004.2	0.70	89250.2	93429.9

[B], [C] is obtained as described in Section 2.3.1 of the WQMP Guidance Document
[E] is obtained from Exhibit A in the WQMP Guidance Document
[G] is obtained from a design procedure sheet, such as in LID BMP Design Handbook and placed in Appendix 6

Section E: Alternative Compliance (LID Waiver Program)

LID BMPs are expected to be feasible on virtually all projects. Where LID BMPs have been demonstrated to be infeasible as documented in Section D, other Treatment Control BMPs must be used (subject to LID waiver approval by the Copermittee). Check one of the following Boxes:

☒ LID Principles and LID BMPs have been incorporated into the site design to fully address all Drainage Management Areas. No alternative compliance measures are required for this project and thus this Section is not required to be completed.

- *Or* -

☐ The following Drainage Management Areas are unable to be addressed using LID BMPs. A site-specific analysis demonstrating technical infeasibility of LID BMPs has been approved by the Co-Permittee and included in Appendix 5. Additionally, no downstream regional and/or sub-regional LID BMPs exist or are available for use by the project. The following alternative compliance measures on the following pages are being implemented to ensure that any pollutant loads expected to be discharged by not incorporating LID BMPs, are fully mitigated.

N/A

E.1 Identify Pollutants of Concern

Utilizing Table A.1 from Section A above which noted your project's receiving waters and their associated EPA approved 303(d) listed impairments, cross reference this information with that of your selected Priority Development Project Category in Table E.1 below. If the identified General Pollutant Categories are the same as those listed for your receiving waters, then these will be your Pollutants of Concern and the appropriate box or boxes will be checked on the last row. The purpose of this is to document compliance and to help you appropriately plan for mitigating your Pollutants of Concern in lieu of implementing LID BMPs.

Table E.1 Potential Pollutants by Land Use Type

Priority Development Project Categories and/or Project Features (check those that apply)	General Pollutant Categories							
	Bacterial Indicators	Metals	Nutrients	Pesticides	Toxic Organic Compounds	Sediments	Trash & Debris	Oil & Grease
☐ Detached Residential Development	P	N	P	P	N	P	P	P
☐ Attached Residential Development	P	N	P	P	N	P	P	P(2)
☐ Commercial/Industrial Development	P(3)	P	P(1)	P(1)	P(5)	P(1)	P	P
☐ Automotive Repair Shops	N	P	N	N	P(4, 5)	N	P	P
☐ Restaurants (>5,000 ft^2)	P	N	N	N	N	N	P	P
☐ Hillside Development (>5,000 ft^2)	P	N	P	P	N	P	P	P
☐ Parking Lots (>5,000 ft^2)	P(6)	P	P(1)	P(1)	P(4)	P(1)	P	P
☐ Retail Gasoline Outlets	N	P	N	N	P	N	P	P
Project Priority Pollutant(s) of Concern	☐	☐	☐	☐	☐	☐	☐	☐

P = Potential

N = Not Potential

(1) *A potential Pollutant if non-native landscaping exists or is proposed onsite; otherwise not expected*

(2) *A potential Pollutant if the project includes uncovered parking areas; otherwise not expected*

(3) *A potential Pollutant is land use involving animal waste*

(4) *Specifically petroleum hydrocarbons*

(5) *Specifically solvents*

(6) *Bacterial indicators are routinely detected in pavement runoff*

E.2 Stormwater Credits

Projects that cannot implement LID BMPs but nevertheless implement smart growth principles are potentially eligible for Stormwater Credits. Utilize Table 3-8 within the WQMP Guidance Document to identify your Project Category and its associated Water Quality Credit. If not applicable, write N/A.

Table E.2 Water Quality Credits

Qualifying Project Categories	Credit Percentage[2]
Total Credit Percentage[1]	

[1]Cannot Exceed 50%
[2]Obtain corresponding data from Table 3-8 in the WQMP Guidance Document

E.3 Sizing Criteria

After you appropriately considered Stormwater Credits for your project, utilize Table E.3 below to appropriately size them to the DCV, or Design Flow Rate, as applicable. Please reference Chapter 3.5.2 of the WQMP Guidance Document for further information.

Table E.3 Treatment Control BMP Sizing

DMA Type/ID	DMA Area (square feet)	Post-Project Surface Type	Effective Impervious Fraction, I_f	DMA Runoff Factor	DMA Area x Runoff Factor		***Enter BMP Name / Identifier Here***		
	[A]		[B]	[C]	[A] x [C]				
						Design Storm Depth (in)	*Minimum Design Capture Volume or Design Flow Rate (cubic feet or cfs)*	*Total Storm Water Credit % Reduction*	*Proposed Volume or Flow on Plans (cubic feet or cfs)*
	$A_T = \Sigma[A]$				Σ= [D]	[E]	$[F] = \frac{[D]x[E]}{[G]}$	[F] X (1-[H])	[I]

[B], [C] is obtained as described in Section 2.3.1 from the WQMP Guidance Document
[E] is obtained from Exhibit A in the WQMP Guidance Document
[G] is for Flow-Based Treatment Control BMPs [G] = 43,560, for Volume-Based Control Treatment BMPs, [G] = 12
[H] is from the Total Credit Percentage as Calculated from Table E.2 above
[I] as obtained from a design procedure sheet from the BMP manufacturer and should be included in Appendix 6

E.4 Treatment Control BMP Selection

Treatment Control BMPs typically provide proprietary treatment mechanisms to treat potential pollutants in runoff, but do not sustain significant biological processes. Treatment Control BMPs must have a removal efficiency of a medium or high effectiveness as quantified below:

- **High**: equal to or greater than 80% removal efficiency
- **Medium**: between 40% and 80% removal efficiency

Such removal efficiency documentation (e.g., studies, reports, etc.) as further discussed in Chapter 3.5.2 of the WQMP Guidance Document, must be included in Appendix 6. In addition, ensure that proposed Treatment Control BMPs are properly identified on the WQMP Site Plan in Appendix 1.

Table E.4 Treatment Control BMP Selection

Selected Treatment Control BMP Name or ID[1]	Priority Pollutant(s) of Concern to Mitigate[2]	Removal Efficiency Percentage[3]

[1] Treatment Control BMPs must not be constructed within Receiving Waters. In addition, a proposed Treatment Control BMP may be listed more than once if they possess more than one qualifying pollutant removal efficiency.
[2] Cross Reference Table E.1 above to populate this column.
[3] As documented in a Co-Permittee Approved Study and provided in Appendix 6.

Section F: Hydromodification

F.1 Hydrologic Conditions of Concern (HCOC) Analysis

Once you have determined that the LID design is adequate to address water quality requirements, you will need to assess if the proposed LID Design may still create a HCOC. Review Chapters 2 and 3 (including Figure 3-7) of the WQMP Guidance Document to determine if your project must mitigate for Hydromodification impacts. If your project meets one of the following criteria which will be indicated by the check boxes below, you do not need to address Hydromodification at this time. However, if the project does not qualify for Exemptions 1, 2 or 3, then additional measures must be added to the design to comply with HCOC criteria. This is discussed in further detail below in Section F.2.

HCOC EXEMPTION 1: The Priority Development Project disturbs less than one acre. The Copermittee has the discretion to require a Project-Specific WQMP to address HCOCs on projects less than one acre on a case by case basis. The disturbed area calculation should include all disturbances associated with larger common plans of development.

Does the project qualify for this HCOC Exemption? ☐ Y ☒ N

If Yes, HCOC criteria do not apply.

HCOC EXEMPTION 2: The volume and time of concentration[1] of storm water runoff for the post-development condition is not significantly different from the pre-development condition for a 2-year return frequency storm (a difference of 5% or less is considered insignificant) using one of the following methods to calculate:

- Riverside County Hydrology Manual
- Technical Release 55 (TR-55): Urban Hydrology for Small Watersheds (NRCS 1986), or derivatives thereof, such as the Santa Barbara Urban Hydrograph Method
- Other methods acceptable to the Co-Permittee

Does the project qualify for this HCOC Exemption? ☐ Y ☒ N

If Yes, report results in Table F.1 below and provide your substantiated hydrologic analysis in Appendix 7.

Table F.1 Hydrologic Conditions of Concern Summary

	2 year – 24 hour		
	Pre-condition	**Post-condition**	**% Difference**
Time of Concentration	N/A	N/A	N/A
Volume (Cubic Feet)	N/A	N/A	N/A

[1] Time of concentration is defined as the time after the beginning of the rainfall when all portions of the drainage basin are contributing to flow at the outlet.

HCOC EXEMPTION 3: All downstream conveyance channels to an adequate sump (for example, Prado Dam, Lake Elsinore, Canyon Lake, Santa Ana River, or other lake, reservoir or naturally erosion resistant feature) that will receive runoff from the project are engineered and regularly maintained to ensure design flow capacity; no sensitive stream habitat areas will be adversely affected; or are not identified on the Co-Permittees Hydromodification Sensitivity Maps.

Does the project qualify for this HCOC Exemption? ☐ Y ☒ N

If Yes, HCOC criteria do not apply and note below which adequate sump applies to this HCOC qualifier:

N/A

F.2 HCOC Mitigation

If none of the above HCOC Exemption Criteria are applicable, HCOC criteria is considered mitigated if they meet one of the following conditions:

a. Additional LID BMPS are implemented onsite or offsite to mitigate potential erosion or habitat impacts as a result of HCOCs. This can be conducted by an evaluation of site-specific conditions utilizing accepted professional methodologies published by entities such as the California Stormwater Quality Association (CASQA), the Southern California Coastal Water Research Project (SCCRWP), or other Co-Permittee approved methodologies for site-specific HCOC analysis.

b. The project is developed consistent with an approved Watershed Action Plan that addresses HCOC in Receiving Waters.

c. Mimicking the pre-development hydrograph with the post-development hydrograph, for a 2-year return frequency storm. Generally, the hydrologic conditions of concern are not significant, if the post-development hydrograph is no more than 10% greater than pre-development hydrograph. In cases where excess volume cannot be infiltrated or captured and reused, discharge from the site must be limited to a flow rate no greater than 110% of the pre-development 2-year peak flow.

Be sure to include all pertinent documentation used in your analysis of the items a, b or c in Appendix 7.

The project will address HCOC's by mitigating the 2-year, 24-hour storm duration flow rates. The proposed bioretention basins have been designed to store the required volume to address HCOC's. During the preliminary stages, the required volume to address the Hydrologic Conditions of Concern was determined by taking the delta 2-year, 24-hour unit hydrograph volumes from the post-project minus the pre-project conditions. Additionally, the water quality volume was also added to determine a total required basin volume. The following tables summarize the results:

		Pre-Project		Post-Project		Post-Pre
	Area (ac)	2-yr 24-hr Q (ft^3/s)	2-yr 24-hr Vol. (ac-ft)	2-yr 24-hr Q (ft^3/s)	2-yr 24-hr Vol (ac-ft)	Delta 2-yr Vol (ac-ft)
DMA A	48.87	1.30	0.8144	4.11	2.5801	1.7657
DMA B	111.68	2.95	1.8609	7.07	4.4662	2.6053

The following table summarizes the basin volumes and required volumes:

Area	Area (AC)	VBMP (sq. ft)	VBMP (ac-ft)	Bottom Surface Area (sq.ft)	Volume @ 0.5' *	Req'd Mitigation Volume	Total Req'd Volume (WQ + Mit) (ac-ft)	Volume Provided (ac-ft)**
DMA A	48.87	39,801	0.9137	32,174	57,913	1.7657	2.6794	3.7150
DMA B	111.68	89,250	2.0489	51,906	93,430	2.6053	4.6542	8.3660

* Volume at 0.5 feet is surface area times 0.5 feet, plus the storage volume within the soil media and gravel layer. The volume within the soil media is equal to the bottom surface area multiplied by 3 feet of depth, and multiplied by 0.3 to account for the 30% void ratio. The volume within the gravel layer below the media is equal to the bottom surface area multiplied by 1 foot of depth, and multiplied by 0.4 to account for the 40% void ratio. This is also calculated on the bioretention basin spreadsheets.

**The volume provided does not include 1’ of freeboard.

The unit hydrograph calculations have been included in Appendix 7.

Section G: Source Control BMPs

Source control BMPs include permanent, structural features that may be required in your project plans — such as roofs over and berms around trash and recycling areas — and Operational BMPs, such as regular sweeping and "housekeeping", that must be implemented by the site's occupant or user. The MEP standard typically requires both types of BMPs. In general, Operational BMPs cannot be substituted for a feasible and effective permanent BMP. Using the Pollutant Sources/Source Control Checklist in Appendix 8, review the following procedure to specify Source Control BMPs for your site:

1. ***Identify Pollutant Sources***: Review Column 1 in the Pollutant Sources/Source Control Checklist. Check off the potential sources of Pollutants that apply to your site.

2. ***Note Locations on Project-Specific WQMP Exhibit***: Note the corresponding requirements listed in Column 2 of the Pollutant Sources/Source Control Checklist. Show the location of each Pollutant source and each permanent Source Control BMP in your Project-Specific WQMP Exhibit located in Appendix 1.

3. ***Prepare a Table and Narrative***: Check off the corresponding requirements listed in Column 3 in the Pollutant Sources/Source Control Checklist. In the left column of Table G.1 below, list each potential source of runoff Pollutants on your site (from those that you checked in the Pollutant Sources/Source Control Checklist). In the middle column, list the corresponding permanent, Structural Source Control BMPs (from Columns 2 and 3 of the Pollutant Sources/Source Control Checklist) used to prevent Pollutants from entering runoff. **Add additional narrative** in this column that explains any special features, materials or methods of construction that will be used to implement these permanent, Structural Source Control BMPs.

4. ***Identify Operational Source Control BMPs:*** To complete your table, refer once again to the Pollutant Sources/Source Control Checklist. List in the right column of your table the Operational BMPs that should be implemented as long as the anticipated activities continue at the site. Copermittee stormwater ordinances require that applicable Source Control BMPs be implemented; the same BMPs may also be required as a condition of a use permit or other revocable Discretionary Approval for use of the site.

Table G.1 Permanent and Operational Source Control Measures

Potential Sources of Runoff pollutants	Permanent Structural Source Control BMPs	Operational Source Control BMPs
On-site storm drain inlets	• Mark all inlets with the words "Only Rain Down the Storm Drain" or similar. Catch Basin Markers may be available from the Riverside County Flood Control and Water Conservation District, call 951.955.1200 to verify.	• Maintain and periodically repaint or replace inlet markings • Provide Stormwater pollution prevention information to new site owners, lessees, or operators. • See applicable optional BMPs in Fact Sheet SC-44, "Drainage System Maintenance," in the CASQA Stormwater Quality Handbooks at www. cabmphandbooks.com • Include the following in lease agreements: "Tenant shall not allow anyone to discharge anything to storm drains or to store or deposit materials so as to create a potential discharge to storm drains."

Potential Sources of Runoff pollutants	Permanent Structural Source Control BMPs	Operational Source Control BMPs
Landscape/Outdoor Pesticide Use	State that final landscape plans will accomplish all of the following. • Preserve existing native trees, shrubs, and ground cover to the maximum extent possible. • Design landscaping to minimize irrigation and runoff, to promote surface infiltration where appropriate, and to minimize the use of fertilizers and pesticides that can contribute to stormwater pollution. • Where landscaped areas are used to retain or detain stormwater, specify plants that are tolerant to saturated soil conditions. • Consider using pest-resistant plants, especially adjacent to hardscape. To insure successful establishment, select plants appropriate to site soils, slopes, climate, sun, wind, rain, land use, air movement, ecological consistency, and plant interactions.	• Maintain landscaping using minimum or no pesticides. • See applicable operational BMPs in "What you should know for…. Landscape and Gardening" at http://rcflood.org/stormwater/. • Provide IPM information to new owners, lessees and operators.
Pools, spas, ponds, decorative fountains, and other water features	• If the Co-Permittee requires pools to be plumbed to the sanitary sewer, place a note on the plans and state in the narrative that this connection will be made according to local requirements.	• See applicable operational BMPs in "Guidelines for Maintaining Your Swimming Pool, Jacuzzi and Garden Fountain" at http://rcflood.org/stormwater/
Roofing, gutters and trim	Avoid roofing, gutters, and trim made of copper or other unprotected metals that may leach into runoff.	
Sidewalks		• Sweep sidewalks regularly to prevent accumulation of litter and debris. Collect debris from pressure washing to prevent entry into storm drain system.
Vehicular Restrictions		• Restrict vehicular onsite power washes • Restrict vehicular onsite maintenance and repairs

Section H: Construction Plan Checklist

Populate Table H.1 below to assist the plan checker in an expeditious review of your project. The first two columns will contain information that was prepared in previous steps, while the last column will be populated with the corresponding plan sheets. This table is to be completed with the submittal of your final Project-Specific WQMP.

Table H.1 Construction Plan Cross-reference

BMP No. or ID	BMP Identifier and Description	Corresponding Plan Sheet(s)
A	Bioretention Basin A	Figure 3 – Site Plan
B	Bioretention Basin B	Figure 3 – Site Plan

Note that the updated table — or Construction Plan WQMP Checklist — is **only a reference tool** to facilitate an easy comparison of the construction plans to your Project-Specific WQMP. Co-Permittee staff can advise you regarding the process required to propose changes to the approved Project-Specific WQMP.

Section I: Operation, Maintenance and Funding

The Copermittee will periodically verify that Stormwater BMPs on your site are maintained and continue to operate as designed. To make this possible, your Copermittee will require that you include in Appendix 9 of this Project-Specific WQMP:

1. A means to finance and implement facility maintenance in perpetuity, including replacement cost.
2. Acceptance of responsibility for maintenance from the time the BMPs are constructed until responsibility for operation and maintenance is legally transferred. A warranty covering a period following construction may also be required.
3. An outline of general maintenance requirements for the Stormwater BMPs you have selected.
4. Figures delineating and designating pervious and impervious areas, location, and type of Stormwater BMP, and tables of pervious and impervious areas served by each facility. Geo-locating the BMPs using a coordinate system of latitude and longitude is recommended to help facilitate a future statewide database system.
5. A separate list and location of self-retaining areas or areas addressed by LID Principles that do not require specialized O&M or inspections but will require typical landscape maintenance as noted in Chapter 5, pages 85-86, in the WQMP Guidance. Include a brief description of typical landscape maintenance for these areas.

Your local Co-Permittee will also require that you prepare and submit a detailed Stormwater BMP Operation and Maintenance Plan that sets forth a maintenance schedule for each of the Stormwater BMPs built on your site. An agreement assigning responsibility for maintenance and providing for inspections and certification may also be required.

Details of these requirements and instructions for preparing a Stormwater BMP Operation and Maintenance Plan are in Chapter 5 of the WQMP Guidance Document.

Maintenance Mechanism: Home Owner's Association

Will the proposed BMPs be maintained by a Home Owners' Association (HOA) or Property Owners Association (POA)?

☒ Y ☐ N

Include your Operation and Maintenance Plan and Maintenance Mechanism in Appendix 9. Additionally, include all pertinent forms of educational materials for those personnel that will be maintaining the proposed BMPs within this Project-Specific WQMP in Appendix 10.

Appendix 1: Maps and Site Plans

Location Map, WQMP Site Plan and Receiving Waters Map

1.0 INTRODUCTION

1.1 Purpose

The purpose of this evaluation was to provide due diligence level preliminary geotechnical information to Anderson Consulting Engineers, Inc. ("Client"), regarding the subject property in the City of Moreno Valley, Riverside County, California. The information developed in this evaluation is intended to provide the Client with an understanding of the physical conditions of site-specific subsurface soils, groundwater, and the regional geologic setting which could affect the cost or design of the proposed development at the subject property (Site Vicinity Map-**Figure 1**, Aerial Site Map-**Figure 2**).

This Due Diligence Preliminary Geotechnical Evaluation has been conducted in general accordance with the accepted geotechnical engineering principles and in general conformance with the approved revised proposal and cost estimate for the project by EEI, dated September 23, 2014.

EEI conducted an onsite field exploration on October 16 and 17, 2014 that included excavation and sampling of four (4) exploratory backhoe trenches and drilling and sampling of four (4) hollow stem auger geotechnical borings for the proposed development at the subject property. Also, three (3) additional shallow borings were drilled to depths of 3 feet or less below the existing ground surface in the areas of proposed detention basins in order to perform field percolation testing. Three (3) additional hollow stem auger geotechnical borings were drilled and sampled for the proposed offsite sewer alignment located approximately ¼ mile south of the main subject property. This Due Diligence Preliminary Geotechnical Evaluation has been prepared for the sole use of Anderson Consulting Engineers, Inc. Other parties, without the express written consent of EEI and the Client should not rely upon this due diligence level preliminary geotechnical evaluation.

1.2 Project Description

We understand that the Client is considering purchasing the subject property for a residential project. Based on a Project Exhibit provided to EEI by Anderson Consulting Engineers, Inc., it appears that the subject property will be developed into approximately 146 residential building pads and associated streets and other improvements. A future offsite sewer extension is proposed for the right-of-way near the southern terminus of Oliver Street approximately ¼ mile south of the subject property. The approximate depth of the proposed sewer is about 25 feet below the existing ground surface within the Eastern Municipal Water District (EMWD) water main right-of-way. No further information is known at this time.

1.3 Scope of Services

The scope of our services included:

- A review of readily available data pertinent to the subject property, including published and unpublished geologic reports/maps, aerial photographs, local groundwater information, and soils data for the area (**References**).
- Conduct a geotechnical reconnaissance of the subject property and nearby vicinity.
- Coordinate with Underground Service Alert to identify the presence of underground utilities for clearance of proposed boring and test pit locations.

- The drilling and logging of four (4) hollow stem auger (HSA) borings (B-1 through B-4) throughout the subject property, ranging from 16 to 50.5 feet below existing grade elevations (bgs). One of the HSA exploratory borings was extended to 50.5 feet bgs for preliminary evaluation of settlement.

- The drilling and logging of three (3) additional hollow stem (HSA) auger borings (B-5 through B-7) in readily accessible areas along the proposed offsite sewer extension near the southern terminus of Oliver Street. The three (3) borings were extended to depths of approximately 26.5 feet below the existing ground surface along the approximate proposed sewer alignment

- Perform field percolation testing at three (3) locations (P-1 through P-3) at depths of approximately 3 feet below the existing ground surface at the locations of proposed detention basins as shown on the Project Exhibit. Testing was performed in general accordance with the County of Riverside guidelines for percolation test methods for preliminary percolation/infiltration information. Percolation testing results are presented in **Table 4**.

- Excavate four (4) exploratory trenches (T-1 through T-4) utilizing a backhoe in readily accessible but widely separated areas of the subject property at depths from approximately 6.5 to 9 feet below the existing ground surface.

- The locations of each of the offsite exploratory borings (for the proposed offsite sewer) are presented on **Figure 2** (Aerial Site Map/Offsite Boring Location Plan). The locations of the exploratory borings, exploratory trenches and percolation test pits on the subject property are presented on **Figure 3** (Field Exploration Plan).

- An evaluation of seismicity and geologic hazards to include an evaluation of faulting.

- Completion of laboratory testing of representative earth materials encountered onsite to ascertain their pertinent soils engineering properties, including corrosion potential (**Appendix B**).

- The preparation of this report which presents our preliminary findings, conclusions, and recommendations.

2.0 BACKGROUND

2.1 Subject Property Description

Based on the information provided by Anderson Consulting Engineers, Inc. ("Client"), and a review of the Google Earth© online database, the subject property consists of approximately 80-acres of undeveloped vacant land located at the northwest corner of the intersection of Oliver Street and Ironwood Avenue, in the City of Moreno Valley, Riverside County, California. Nason Street forms the majority of the western boundary; Ironwood borders the south; and Oliver Street forms the eastern boundary. Vacant land is present to the north. In general, the area is characterized by rural residential and vacant land. Proposed development is for multi or single-family residential.

We understand that an offsite sewer alignment is proposed which is located approximately ¼ miles south of the main subject property area. The sewer alignment is proposed to be extended approximately 900 feet to the south from the existing terminus on Oliver Street near the intersection with Carol Place.

The subject property is approximately situated at 33.9448° north latitude and 117.1871° west longitude (GoogleEarth®, 2013).

2.2 Site Topography

A review of the Sunnymead, California 7.5-minute topographic quadrangle (USGS, 2012) and Project Exhibit/topographic map prepared by Anderson Consulting Engineers, Inc. indicates that the subject property elevation varies from approximately 1,840 to 1,980 feet above mean sea level (amsl). From east-west across the property is a series of north-south oriented ridges and alternating drainage gullies in the lower, southern portion of the property. The intervening ridges are generally about 5 to 10 feet higher in elevation than the adjacent drainage gullies. Rounded granitic outcrops are exposed in the northwestern and northeastern sections of the subject property. The site topography can be generally described as a relatively well-dissected alluvial fan descending from the eroded hills to the north. The overall surface gradient across the property is gently to moderately south or south-southeast.

2.3 Geologic Setting

The subject property and vicinity lies within the Peninsular Ranges Geomorphic Province of California (CGS, 2002). The Peninsular Ranges Geomorphic Province extends from the Transverse Ranges Geomorphic Province and the Los Angeles Basin, south to Baja California. This province varies in width from about 30- to 100-miles. It is bounded on the west by the Pacific Ocean, on the south by the Gulf of California and on the east by the Colorado Desert Province. The Transverse Ranges Geomorphic Province bounds the Peninsular Ranges on the north. The Peninsular Ranges are essentially a series of northwest-southeast oriented fault blocks. Major fault zones and subordinate fault zones found in the Peninsular Ranges Province typically trend in a northwest-southeast direction.

Regional geologic maps of the subject property vicinity (Morton et al., 2004) indicate the property is underlain by Cretaceous-age plutonic rocks composed of tonalite and Holocene age Younger Alluvial Fan deposits. Outcroppings of the weathered tonalite bedrock are exposed in the northwestern and northeastern portions of the property. Over the remainder of the property, the tonalite bedrock was found to be weathering into a soil with a "decomposed granite" or "dg" texture at depth in the exploratory borings and trenches and in general is covered with several feet of alluvial and colluvial (younger alluvial fan) soils also derived from the weathered tonalite. The alluvial and colluvial soils are generally comprised of relatively loose to dense silty sand. The property is relatively undeveloped and artificial fill was not encountered during our field exploration at the property.

Due to the proximity of the subject property area to several nearby active faults, strong ground shaking could occur at the property as a result of an earthquake on any one of the faults. Our review indicates that there are no known active faults crossing the property and the property is not within a State of California Earthquake Fault Zone (Jennings, 1994; Hart and Bryant, 1997, CDMG, 1974; 1998). Due to the presence of shallow bedrock and the lack of shallow groundwater at the property, the property is considered as having a low susceptibility to liquefaction.

2.4 Regional Groundwater

A seismic hazard zone map and report have not been completed for the Sunnymead Quadrangle, therefore, the depth to the historic high groundwater at the subject property is not known. Due to the presence of relatively shallow granitic bedrock at the property, static groundwater is not expected and groundwater was not encountered in any of the exploratory borings or trenches excavated at the property to a maximum explored depth of 50.5 feet below the existing ground surface. Within the lower drainage gullies, up to 30 feet in thickness of silty sand alluvium was encountered. Although not encountered within the alluvium during our field excavation, during times of heavy precipitation or runoff, a localized perched groundwater condition could exist. A review of topographic maps of the general vicinity of the subject property indicates regional topographic relief slopes gently towards the south or south-southeast.

This information suggests that regional groundwater in the property vicinity could be inferred to flow in the same general topographic direction.

3.0 FAULTING AND SEISMICITY

The portion of Southern California that includes the subject property is considered to be seismically active. Due to the proximity of the property area to several nearby active faults, strong ground shaking could occur at the property as a result of an earthquake on any one of the faults. Our review indicates that there are no known active faults crossing the property (Blake, 2000) and the property is not within an Earthquake Fault Zone (Hart and Bryant, 1997). It is our opinion, therefore, that the likelihood of surface fault rupture at the property is low. **Table 1** lists the major active faults within 25 miles that are likely to affect the property.

TABLE 1
Summary of Major Active Faults

	Fault Name	Approximate Distance From Site miles (kilometers)	Maximum Moment Magnitude
1	San Jacinto-San Jacinto Valley	1.5 (2.4)	6.9
2	San Jacinto-San Bernardino	5.8 (9.3)	6.7
3	San Andreas – San Bernardino M-1	12.1 (19.5)	7.5
4	San Andreas – SB-Coach. M-2b	12.1 (19.5)	7.7
5	San Andreas – SB-Coach. M-1b-2	12.1 (19.5)	7.7
6	San Andreas – Whole M-1a	12.1 (19.5)	8.0
7	North Frontal Fault Zone (West)	19.4 (31.2)	7.2
8	San Jacinto – Anza	21.0 (33.8)	7.2
9	Elsinore (Glen Ivy)	21.7 (35.0)	6.8
10	Cucamonga	21.9 (35.2)	6.9
11	Elsinore (Temecula)	22.8 (36.7)	6.8
12	Cleghorn	23.1 (37.2)	6.5
13	Chino-Central Ave. (Elsinore)	23.3 (37.5)	6.7

3.1 Seismic Parameters and Peak Ground Acceleration

Maximum considered ground motion maps provided in the California Building Code (CBC, 2013) were utilized with coordinates of 33.9448° north latitude and 117.1871° west longitude, to determine the subject property seismic parameters. EEI utilized seismic design criteria provided in the CBC (2013).

In accordance with the guidelines of the CBC (2013), the spectral parameters for the subject property (based on a Site Class B soil) are estimated to be $S_s = 2.166g$ and $S_1 = 0.982g$. Review of the geotechnical data obtained during our subsurface exploration, however, indicates that the property should be classified as Class D per the CBC (Table 1613.5.2). Consequently, Site Coefficients $F_a = 1.000$ and $F_v = 1.500$ appear to be appropriate for the property. Based on this information, the adjusted maximum considered earthquake spectral response parameters $S_{MS} = 2.166g$ and $S_{M1} = 1.472g$ are recommended for seismic design of the project. Assuming an occupancy category of II (Table 1604A.5), an S_{DS} value of 1.444g and an S_{D1} value of 0.982g, the proposed building at the property can be assigned a seismic design category of D [Table 1613.5.6 (1) and (2)]. Final selection of the appropriate seismic design coefficients should be made by the structural consultant based on the local laws and ordinances, expected building response, and desired level of conservatism.

Seismic Hazard Response Parameters are listed in **Table 2**.

TABLE 2
Seismic Hazard Response Parameters and Design Parameters CBC (2013)

Latitude: 33.9448° - Longitude: -117.1871° Seismic Parameter	Period (Sec)		Value
Mapped Spectral Acceleration Value, Soil Class B	0.2	S_s	2.166g
Mapped Spectral Acceleration Value, Soil Class B	1.0	S_1	0.982g

Building Assigned Seismic Design Category per Table 1613.5.6 (1) and (2)	--	--	D

3.2 Ground Lurching or Shallow Ground Rupture

Based on the geography, topography and site-specific geotechnical conditions encountered during our preliminary geotechnical evaluation at the subject property, we consider the potential for ground lurching or shallow ground rupture at the property to be low; however, due to the active seismicity of California, this possibility cannot be completely ruled out. In light of this, the unlikely hazard of lurching or ground-rupture should not preclude consideration of "flexible" design for onsite utility lines and connections.

3.3 Liquefaction

Liquefaction is a phenomenon in which the strength and stiffness of a soil is reduced by earthquake shaking or other rapid loading. Liquefaction and related phenomena have been responsible for substantial structural damage in historical earthquakes, and are a design concern under certain conditions. Liquefaction occurs in saturated soils that are soils in which the space between individual particles is completely filled with water. This pore water exerts a pressure on the soil particles that influences how tightly the particles themselves are pressed together.

Prior to an earthquake, pore water pressure is typically low; however, earthquake motion can cause the pore water pressure to increase to the point where the soil particles can readily move with respect to each other. When liquefaction occurs; the strength of the soil decreases and the ability of a soil deposit to support structural loads are reduced.

A seismic hazard zone map and report for the Sunnymead Quadrangle has not been issued by the California Geological Survey (CGS) so the subject property is, therefore, not situated within a mapped Liquefaction Zone. The majority of the property is underlain by generally loose to medium dense alluvial and colluvial deposits that overlie relatively shallow granitic bedrock. The alluvial and colluvial soils are subject to removal and recompaction during site grading for the proposed residential development. It appears that liquefaction is not a significant geotechnical concern at the property.

Cyclic mobility is a liquefaction phenomenon, triggered by cyclic loading, occurring in soil deposits with static shear stresses lower than the soil strength. Deformations due to cyclic mobility develop incrementally because of static and dynamic stresses that exist during an earthquake. Lateral spreading, a common result of cyclic mobility, can occur on gently sloping and on flat ground close to rivers and lakes. These conditions do exist within the subject property, however, based on the conceptual site plan, the property should be relatively level following rough grading with a lack of free channel faces and cyclic mobility should not be an issue post-grading.

3.4 Seismic Induced Settlement

Seismically induced settlement can occur due to reorientation of soil particles during strong shaking of unsaturated sands, as well as in response to liquefaction of saturated loose granular soils.

Based on our evaluation and the geotechnical data obtained from our exploratory borings and trenches, we estimate the total seismic-induced settlement to be less than 1-inch. Differential earthquake induced settlements are estimated to be less than 0.5-inches over a 50-foot span.

4.0 FIELD EXPLORATION AND LABORATORY TESTING

4.1 Field Exploration

Field work for our geotechnical evaluation was conducted on October 16 and 17, 2014. A total of four (4) hollow stem auger borings were drilled on the subject property. Boring depths ranged from 11 feet to 50.5 feet below the existing ground surface. Three (3) additional hollow stem auger borings were drilled offsite in the area of the proposed sewer line extension. All three borings were drilled to an approximate depth of 26.5 feet below existing grade. In addition to the hollow stem auger borings, four (4) exploratory backhoe trenches were excavated on the subject property to depths ranging from 6.5 to 9 feet below existing grade. All exploratory borings and trenches were logged under the supervision of a Registered Professional Engineer and/or Certified Engineering Geologist at EEI. Boring and trench locations were adjusted as necessary due to existing utilities and improvements.

Blow count (N) values were determined utilizing a 140 pound automatic hammer, falling 30-inches onto a Standard Penetration Test (SPT) split-spoon sampler and a Modified California split-tube sampler. A truck mounted hollow-stem auger (HSA) drill rig and rubber-tired backhoe were used during field work. The blows per foot (N value) required to advance the 18-inch long SPT and 12-inch long Modified California split-tube samplers was measured at various initial depths followed by 5-foot intervals, recorded on the boring logs. The boring logs and trench logs for the field exploration are presented in **Appendix A**-Soil Classification Chart and Boring & Trench Logs. Relatively "undisturbed" samples were collected in a 2.42-inch (inside diameter) California Modified split-tube sampler for visual examination and laboratory testing in the exploratory borings. The soils were classified in accordance with the Unified Soil Classification System (ASTM, 2008). Representative bulk samples were also collected from both the exploratory borings and trenches for appropriate laboratory testing.

4.2 Subsurface Conditions

The results of our geotechnical exploration indicate that the proposed residential development is underlain by weathered Cretaceous-age plutonic rocks composed of tonalite. This material was observed to extend beyond the maximum depth of our exploratory borings and test pits (approximately 50.5 feet below existing grades). Alluvial soils up to 30 feet thick were observed to mantle the weathered tonalite bedrock within the lower lying channel/drainage areas.

On the higher, elevated ridge areas on the subject property, colluvial soils were observed to mantle the weathered tonalite bedrock with a thickness varying between 3 and 14 feet. The weathered tonalite bedrock can generally be described as gray, white or black speckled or orange to dark grayish-orange (depending on degree of weathering) with a "granitic" or phaneritic texture and was generally unweathered to highly weathered. Outcroppings of the weathered tonalite bedrock are exposed in the northwestern and northeastern portions of the site. Over the remainder of the property, the tonalite bedrock was found to be weathering into a medium dense to very dense silty sand soil with a "decomposed granite" or "dg" texture at depth in the exploratory borings and test pits. The alluvial and colluvial (younger alluvial fan) soils are also derived from the weathered tonalite. The alluvial and colluvial soils are generally comprised of orange-brown or red-brown, medium brown or light gray brown, fine to coarse, damp to moist, loose to dense silty sand. The property is relatively undeveloped and artificial fill was not encountered during our field exploration at the property.

Our exploratory excavations were performed utilizing light-duty equipment which can provide general excavation characteristics of the onsite materials. Large granitic (tonalite) bedrock outcrops are present on the northeast and northwest portions of the property, along with some isolated rock outcrops within the areas of the proposed development area and generally on the higher elevations of the property. Boulders were present at the surface in these areas, some localized "core rock or floaters" should be anticipated at variable depths in these areas. Based on observed subsurface conditions in the exploratory trench excavations and borings, the "decomposed granite" or "dg" is moderately to highly weathered and/or fractured and was relatively easy to excavate to the depths indicated with a light-duty backhoe and a drill rig equipped with flight auger equipment. No refusal was encountered in any of the exploratory excavations during our field exploration.

In general, the ease of rock excavation or rippability depends on various factors such as rock type, rock hardness and density, the amount of weathering, and the existence and characteristics of discontinuities such as joint spacing, foliation, or fractures.

Due to the relatively dense character of the granitic bedrock encountered onsite, it is likely that oversized rock materials will be created during grading operations. Native earth materials appear to be suitable for use as structural fill provided they are moisture conditioned (as needed), meet EEI's recommendations for size (Section 4.2.2 Fills), and are properly compacted. Dependent upon the grading plan, some of the oversized materials may be re-used in landscape areas.

For the proposed offsite sewer line location, weathered tonalite overlain by 15 feet of alluvial soils was encountered in boring B-5. In boring B-6, colluvial soils at depth were mantled by approximately 10 feet of artificial fill. For boring B-7, colluvial soils were encountered from the surface to the total explored depth. All three offsite borings were advanced to a total depth of 26.5 feet below the existing ground surface. The weathered tonalite bedrock and alluvial soils are generally unchanged from the materials encountered on the subject property. The offsite colluvial soils can generally be described as orange brown to brown, fine to coarse, moist, medium dense to dense silty sand and sandy silt. The artificial fill soils encountered can be described as light brown, fine to coarse, and damp, medium dense silty sand. Refusal was not encountered within any of our exploratory borings or test pits. Detailed descriptions of the encountered soils are provided on the boring logs and test pit logs included as **Appendix A.**

Due to the presence of relatively shallow granitic bedrock at subject property, static groundwater is not expected and groundwater was not encountered in any of the exploratory borings or trenches excavated at the property to a maximum explored depth of 50.5 feet below the existing ground surface. Our review of ground water monitoring data from nearby wells suggests that the groundwater level may fluctuate seasonally and yearly.

It should be noted that fluctuations in the ground water level could also occur due to variations in ground surface topography, subsurface stratifications, precipitation, irrigation, and other factors which may not have been evident at the time of our exploration.

4.3 Laboratory Testing and Classification

Representative samples were selected for laboratory testing to confirm their field classification(s). Field descriptions and classifications were visually classified according to the American Society for Testing and Materials (ASTM) D2488 which classifies soils under the Unified Soil Classification System (USCS). Representative soil samples were tested in the lab for grain size distribution, liquid limits, and plastic limits to determine actual classifications by ASTM D2487-Standard Practice for Classification of Soils for Engineering Purposes in accordance to the USCS. Final classifications of soils can be found on the boring logs in **Appendix A** and the laboratory test data in **Appendix B**.

4.3.1 Moisture Content and Dry Density

The in-situ moisture content and dry density of soils were determined for soil samples obtained from the borings. Moisture contents and dry densities of soils help to determine engineering design parameters for foundations, retaining walls, and other engineered structures. Moisture content on soil samples was conducted in general accordance with ASTM D2216, and was recorded as a percentage. In-situ moisture content and dry density information for soil samples retrieved from the field can be found on the boring logs located in **Appendix A**.

4.3.2 Grain Size Distribution

To help check field classifications of soils, the grain size distribution of representative soil samples was determined. In order to find the percentages of different sized particles in a particular soil stratum, soils were tested in general accordance with ASTM D422-Standard Test Method for Particle-Size Analysis of Soils. Grain size distribution curves and gradation results are presented in **Appendix B.**

4.3.3 Maximum Dry Density and Optimum Moisture Content

The maximum dry density and optimum moisture content were determined from a bulk sample obtained from boring B-1 at depths between 0 and 5 feet below existing grade. Our testing was performed in general accordance with ASTM D1557, Method A. Results of our testing are presented in **Appendix B**.

4.3.4 Direct Shear

Direct shear testing was conducted on three representative samples of the upper soils. One sample was remolded to 90 percent of their maximum dry density (based on ASTM D1557), and the other two samples in its natural state, to measure its shear strength characteristics for engineering purposes. The samples were inundated for at least 18 hours. The samples were placed in a shear box and a normal load was applied (10, 20, and 40 kilogram weights were used). The samples were then sheared at a controlled strain rate in a direct shear apparatus that measures horizontal displacement and shear resistance. Shear testing was run in general accordance with ASTM D3080. The results of our testing are presented in **Appendix B**.

4.3.5 Expansion Index

A soil sample from boring B-1 within the upper 5 feet of existing grade was tested for its expansion potential. Our expansion index testing was conducted in general accordance with ASTM D4829. The results of our expansion index testing are presented in **Appendix B.**

4.3.6 Sulfate/Corrosion

One representative sample of onsite earth material was collected for analysis at Clarkson Laboratory and Supply, Inc. located in Chula Vista, California for corrosion/soluble sulfate potential. This corrosion testing included soil minimum resistivity and pH by California Test 643, sulfate by California Test 417, and chloride by California Test 422. Results of these tests are presented in **Appendix B**.

It should be understood that the results provided in **Appendix B** are based upon pre-development conditions. Verification testing is recommended at the conclusion of grading on samples collected at or near finish grade.

5.0 CONCLUSIONS

Based on our field exploration, laboratory testing and engineering and geologic analysis, it is our opinion that the subject property is suitable for the proposed new development and associated improvements from a geotechnical engineering and geologic viewpoint; however, there are existing geotechnical conditions associated with the property that will warrant mitigation and/or consideration during planning stages. If site plans and/or the location of the proposed residential buildings or proposed offsite sewer line are revised, additional field studies may be warranted to address proposed site-specific conditions. As a result, EEI is providing the following conclusions:

- A total of four (4) hollow stem auger borings were drilled on the subject property. Boring depths ranged from 11 feet to 50.5 feet below the existing ground surface. Three (3) additional hollow stem auger borings were drilled offsite in the area of the proposed sewer line extension. All three borings were drilled to an approximate depth of 26.5 feet below existing grade. In addition to the hollow stem auger borings, four (4) exploratory backhoe trenches were excavated on the subject property to depths ranging from 6.5 to 9 feet below existing grade. The subject property is underlain by weathered Cretaceous-age plutonic rocks composed of tonalite. This material was observed to extend beyond the maximum depth of our exploratory borings and test pits (approximately 50.5 feet below existing grades). Alluvial soils up to 30 feet thick were observed to mantle the weathered tonalite bedrock within the lower lying channel/drainage areas. On the higher, elevated ridge areas on the subject property, colluvial soils were observed to mantle the weathered tonalite bedrock with a thickness varying between 3 and 14 feet. The weathered tonalite bedrock was can generally be described as gray, white or black speckled or orange to dark grayish-orange (depending on degree of weathering) with a "granitic" or phaneritic texture and was generally unweathered to highly weathered and very soft to moderately hard. The alluvial and colluvial (younger alluvial fan) soils are also derived from the weathered tonalite. The alluvial and colluvial soils are generally comprised of orange-brown or red-brown, medium brown or light gray brown, fine to coarse, damp to moist loose to dense silty sand.

- On the subject property, the weathered tonalite bedrock was observed to be mantled by up to approximately a 30-foot thick layer of alluvium in the lower drainage/wash areas while a relatively thin layer of colluvial soils, also mainly silty sand was observed in the exploratory borings and test pits on the higher "ridges".

- For the proposed offsite sewer line location, weathered tonalite overlain by 15 feet of alluvial soils was encountered in boring B-5. In boring B-6, colluvial soils at depth were mantled by approximately 10 feet of artificial fill. For boring B-7, colluvial soils were encountered from the surface to the total explored depth. All three offsite borings were advanced to a total depth of 26.5 feet below the existing ground surface. The weathered tonalite bedrock and alluvial soils are generally unchanged from the materials encountered on the subject property. The offsite colluvial soils can generally be described as orange brown to brown, fine to coarse, moist, loose to medium dense silty sand and sandy silt. The artificial fill soils encountered can be described as light brown, fine to coarse, and damp, loose to medium dense silty sand. No refusal was encountered in any of the onsite or offsite exploratory boring or test pit locations.

- We understand that the Client is considering purchasing the subject property for a residential project. Based on a Project Exhibit provided to EEI by Anderson Consulting Engineers, Inc., it appears that the subject property will be developed into approximately 146 residential building pads and associated streets and other improvements. A future offsite sewer extension is proposed for the right-of-way near the southern terminus of Oliver Street approximately ¼ south of the subject property. The approximate depth of the proposed sewer is about 25 feet below the existing ground surface within the Eastern Municipal Water District (EMWD) water main right-of-way. No further information is known at this time.

- Groundwater was not encountered in any of our onsite or offsite exploratory borings or exploratory test pits to the depths explored (approximately 50.5 feet below existing grades). It should be noted that variations in groundwater may result from fluctuations in the ground surface topography, subsurface stratification, precipitation, irrigation and other factors that may not have been evident at the time of our subsurface exploration.

- Laboratory test results indicate that the near surface materials are near neutral (pH = 7.1) and are moderately corrosive to ferrous metals with a minimum resistivity value of 5,200 ohm-cm. Laboratory testing of the upper soils yielded a soluble sulfate concentration of 0.005 percent and a chloride concentration of 0.007 percent, indicating a negligible corrosion potential to reinforced concrete.

- The results of our laboratory Expansion Index (EI) testing indicate an expansion index of 0, for the tested soils which represents a very low expansion potential.

- The subject property is located within an area of Southern California recognized as having a number of active and potentially-active faults. Our review indicates that there are no known active faults crossing the property and the property is not located within an Earthquake Fault Zone. The nearest active faults that could affect the property are the San Jacinto Valley segment of the San Jacinto Fault Zone, located approximately 1.5 miles from the property, the San Bernardino segment of the San Jacinto Fault Zone, located approximately 5.8 miles from the area of study, the San Bernardino M-1 segment of the San Andreas Fault Zone, the San Bernardino-Coachella Valley M-2b segment of the San Andreas Fault Zone, the San Bernardino-Coachella Valley M-1b-2 segment of the San Andreas Fault Zone and the San Bernardino-Coachella Valley M-1a segment of the San Andreas Fault Zone, all located approximately 12.1 miles from the area of study. Each of these active faults is capable of generating severe ground shaking at the property. A list of active faults within an approximate 25 mile radius is presented in **Table 1**.

- Based on EEI's evaluation, earth materials underlying the subject property are not considered susceptible to liquefaction or significant amounts of seismic settlement. Based on EEI's evaluation, the earth materials underlying the subject property of the proposed development appear to be susceptible to some seismically induced settlement on the order of less than one-inch with differential settlements of less than 0.5-inches over a 50-foot span. Liquefaction-induced lateral spreading does not appear to be a concern at the subject property due to the lack of shallow groundwater, the lack of nearby open face channels and the relatively shallow depth to bedrock.

- At this time and for the purposes of this Due Diligence Level Preliminary Evaluation, we cannot present specific footing recommendations that can be incorporated in the structural design, given that we do not have a scope of the proposed project, no grading or foundation plans were available at the time and no information was provided to us other than the Client is considering purchasing the property for future development.

6.0 RECOMMENDATIONS

The recommendations presented herein should be considered as preliminary for the purpose of characterizing the geotechnical and geologic conditions at the subject property prior to purchasing the property, and for preliminary information to aid the initial planning and design phases of development. Guidelines for site preparation, earthwork, and onsite improvements are provided in the following sections based on a limited number of widely spaced exploratory borings and test pits, and the assumption that the planned onsite development will consist of single-family, wood-frame, slab-on-grade 1- to 2-story residential structures and the planned offsite construction for the proposed sewer line. For more detailed and specific recommendations for the design and planning of the proposed structures at the property, we recommend to supplement this Due Diligence Level Preliminary Geotechnical Evaluation with an additional Geotechnical Evaluation. This additional Geotechnical Evaluation would include a supplementary subsurface evaluation, incorporating additional hollow stem auger borings (HSA), to identify more specifically and in areas not covered by this Due Diligence Level Preliminary Geotechnical Evaluation, the subject property's subsurface conditions and other zones potentially susceptible to seismically induced settlement to the depths explored.

6.1 General

Grading should conform to the guidelines presented in the 2013 California Building Code (CBC, 2013), as well as the requirements of the City of Moreno Valley and the County of Riverside. Additionally, general Earthwork and Grading Guidelines are provided herein as **Appendix C**.

During earthwork construction, removals and reprocessing of fill materials, as well as general grading procedures of the contractor should be observed and the fill placed selectively tested by representatives of the geotechnical engineer, EEI. If any unusual or unexpected conditions are exposed in the field, they should be reviewed by the Geotechnical Engineer and if warranted, modified and/or additional remedial recommendations will be offered. Specific guidelines and comments pertinent to the planned development are provided herein.

The recommendations presented herein have been completed using the preliminary information provided to us regarding site development. If information concerning the proposed development is revised, or any changes in the design and location of the proposed property improvements are made, the preliminary conclusions and recommendations contained in this report should not be considered applicable unless the changes are reviewed and conclusions of this report modified or approved in writing by this office.

6.2 Site Preparation and Grading

Debris and other deleterious material, such as organic soils and/or environmentally impacted earth materials should be removed from the subject property prior to the start of grading. Areas to receive fill should be properly benched in accordance with current industry standards of practice and guidelines specified in the CBC and the requirements of the local jurisdiction.

Existing utilities should be removed within the proposed building envelope. Abandoned trenches should be properly backfilled and tested. If unanticipated subsurface improvements (utility lines, septic systems, wells, utilities, etc.) are encountered during earthwork construction, the geotechnical engineer should be informed and appropriate remedial recommendations would then be provided.

6.3 Remedial Earthwork

The encountered portions of the existing surficial soils including the upper portions of the alluvial and colluvial soils were observed to be somewhat loose and variable in moisture content and relative density. As such, they are considered potentially compressible and unsuitable for the support of settlement-sensitive structures or engineered fill in their current condition. Therefore, where not already removed by the proposed site grading, the existing materials should be completely removed and recompacted in the areas to receive the proposed building improvement and other settlement-sensitive improvements. Based on the results of our subsurface exploration, we recommend that these removals extend to approximate depths on the order of a minimum of 4 feet to a maximum of 30 feet below the existing ground surface, or 24-inches below the bottoms of the proposed foundations. At the approximate location of boring B-1, 30 feet of relatively loose to medium dense silty sand alluvium was encountered above the tonalite bedrock and should be removed to a depth of 30 feet. A similar situation likely exists in other, lower elevation portions of the site within the drainage channels.

Following removal of the upper soils, the bottom of the resulting excavation(s) should be observed by a representative of EEI to check that unsuitable materials have been sufficiently removed. It should be understood that based on the observations of our field representative, localized deeper removals may be recommended. The base of the removal area should be level to avoid differential fill thicknesses under proposed improvements. This remedial earthwork should extend at least 5 feet outside the proposed building limits and/or 5 feet beyond the area to receive fill. Note that vertical sides exceeding 5 feet in depth may be prone to sloughing and may require laying back to an inclination of 1:1 (horizontal to vertical).

After removal of the upper soils and observation of the excavation bottoms, the over-excavated areas should be scarified to a minimum depth of 6-inches, moisture conditioned as needed to achieve at least optimum moisture content and re-compacted to at least 90 percent of the maximum dry density (based on ASTM D1557). The over-excavated areas should then be backfilled with onsite and/or imported soils that are placed and compacted as recommended herein until design finish grades are reached.

6.4 Yielding Subgrade Conditions

The soils encountered at the subject property can often exhibit "pumping" or yielding once they become saturated. This can often occur in response to periods of significant precipitation, such as during the winter rainy season, or if the bottom of an excavation is situated relatively close to the groundwater level. In order to help stabilize the yielding subgrade soils within the bottom of the removal areas, the contractor can consider the placement of uniform sized, ¾- to 2-inch crushed rock within areas exhibiting the "pumping" conditions. The crushed rock should be properly tracked into the underlying soils such that it is adequately intruded into and interlocks with the soils. We expect that a 6- to 12-inch thick section of the crushed rock will be required.

Following the placement and tracking of the gravel layer into the underlying "pumping" soils, it is recommended that Mirafi 600X stabilization fabric (or approved equivalent) then be placed upon the gravel layer. Fill soils, which should be placed and compacted in accordance with the recommendations presented herein, should then be placed upon the fabric until design finish grades are reached. The gravel and stabilization fabric should extend at least 5 feet laterally beyond the limits of the "pumping" areas. These operations should be performed under the observation and testing of a representative of EEI in order to evaluate the effectiveness of these measures and to provide additional recommendations for mitigative measures, as warranted.

6.5 Fill Placement

The soils encountered at the subject property can often exhibit "pumping" or yielding once they become saturated. This can often occur in response to periods of significant precipitation, such as during the winter rainy season, or if the bottom of an excavation is situated relatively close to the groundwater level. In order to help stabilize the yielding subgrade soils within the bottom of the removal areas, the contractor can consider the placement of uniform sized, ¾- to 2-inch crushed rock within areas exhibiting the "pumping" conditions. The crushed rock should be properly tracked into the underlying soils such that it is adequately intruded into and interlocks with the soils. We expect that a 6- to 12-inch thick section of the crushed rock will be required. Following the placement and tracking of the gravel layer into the underlying "pumping" soils, it is recommended that Mirafi 600X stabilization fabric (or approved equivalent) then be placed upon the gravel layer. Fill soils, which should be placed and compacted in accordance with the recommendations presented herein, should then be placed upon the fabric until design finish grades are reached. The gravel and stabilization fabric should extend at least 5 feet laterally beyond the limits of the "pumping" areas. These operations should be performed under the observation and testing of a representative of EEI in order to evaluate the effectiveness of these measures and to provide additional recommendations for mitigative measures, as warranted.

If import soils are needed, the earthwork contractor should ensure that all proposed fill materials are approved by the Geotechnical Engineer prior to use. Representative soil samples should be made available for testing at least ten working days prior to hauling to the subject property to allow for laboratory tests.

Fill materials should be placed in 6- to 8-inch loose lifts, moisture conditioned as necessary to at least optimum moisture and compacted to a minimum of 90 percent maximum density according to ASTM D1557. The upper 12-inches of pavement subgrade should be moisture conditioned to at least optimum moisture and compacted to at least 95 percent of the maximum dry density as determined by ASTM D1557. Suitable heavy grading equipment should be utilized to properly mix, spread, moisture condition or dry, and compact each fill lift.

Those areas to receive fill (including over-excavated areas) or surface improvements should be scarified at least 6-inches, moisture conditioned to at least one percent over optimum moisture content and recompacted to at least 90 percent of the maximum dry density (based on ASTM D1557).

6.6 Shrinkage and Bulking

Several factors will impact earthwork balancing on the subject property, including shrinkage, bulking, subsidence, trench spoils from utilities and footing excavations, and final pavement section thickness as well as the accuracy of topography.

Shrinkage, bulking and subsidence are primarily dependent upon the degree of compactive effort achieved during construction. For planning purposes, the shrinkage factor is estimated to be on the order of 10 to 15 percent for the onsite natural soils to be utilized as fill. This shrinkage factor may vary with methods employed by the contractor. Subsidence is estimated to be on the order of 0.1 feet. For preliminary planning purposes, bulking of the granitic bedrock derived materials is estimated to be 0 to 10 percent. Losses from site clearing and removal of existing site improvements as well as generation of oversize material may affect earthwork quantity calculation and should be considered.

The previous estimates are intended as an aid for the project engineers in estimating earthwork quantities. It is recommended that the site development be planned to include an area that could be raised or lowered to accommodate final site balancing.

7.0 PRELIMNARY FOUNDATION RECOMMENDATIONS

7.1 General

The conclusions and recommendations presented herein, are based on the assumption that the planned development will consist of two- to four-story wood frame residential structures with slab-on-grade. It is our understanding that these conceptual plans are also part of the due diligence phase of the project and may or may not be the final design. As such, the conclusions and recommendations contained in this Due Diligence Preliminary Geotechnical Evaluation report should be considered preliminary, and should be reviewed, revised and/or approved in writing by EEI at the time the project design is finalized.

Be advised that as part of the foundation design election process, there is always a cost/benefit evaluation. Although we are providing alternatives for foundation design we have not accomplished the cost/benefit evaluation.

7.2 Preliminary Foundation Design

Lightly loaded wood-frame, two- to four-story residential buildings with a slab-on-grade, can be supported on conventional continuous or isolated spread footings bearing upon at least 24-inches of properly compacted fill materials. In preparation for foundation construction, the earthwork contractor should ensure that the site has been prepared as recommended, and that field density tests have been performed to adequately document the relative compaction of the structural fill.

Conventional foundations can be designed to impose dead plus long term live load bearing pressures of 2,000 pounds per square foot (psf). The allowable foundation bearing pressure is for footings having a minimum width of 15-inches and a minimum depth of 18-inches embedment below the lowest adjacent finish grade for one or two story buildings and 18-inches wide and a minimum 24-inches embedment below lowest adjacent finish grade for three or four-story buildings. The allowable soil bearing pressure can be increased by one-third when considering transient loads of short duration, such as wind or earthquake loads. Based on the prevailing geotechnical conditions encountered during our subsurface exploration, we recommend that foundations be reinforced with at least two No. 4 bars placed at the top of the footing and two placed at the bottom.

Horizontal loads acting on foundations and stem walls cast in open excavations against undisturbed native soil or against properly placed and compacted fill will be resisted by friction acting along the base of the footing and by passive earth pressures against the side of the footing and stem wall. The frictional resistance acting along the base of footings founded on suitable foundation soils may be computed using a coefficient of friction equal to 0.30 with the normal dead load.

Passive earth pressures acting against the side of footings and stem walls may be assumed to be equivalent to a fluid weighing 250 pounds per cubic foot. Passive pressure in the upper 1.0-foot should be neglected unless confined by concrete slabs-on-grade or asphalt concrete pavement. The values given above may be increased by one-third for transient wind or seismic loads.

7.3 Footing Setbacks

All footings should maintain a minimum 7-foot horizontal setback from the base of the footing to any descending slope (if existing onsite). This distance is measured from the outside footing face at the bearing elevation. Footings should maintain a minimum horizontal setback of H/3 (H=slope height) from the base of the footing to the descending slope face and no less than seven feet, or greater than 40 feet.

Footings adjacent to unlined drainage swales or underground utilities (if any) should be deepened to a minimum of 6-inches below the invert of the adjacent unlined swale or utilities. This distance is measured from the footing face at the bearing elevation. Footings for structures adjacent to retaining walls should be deepened so as to extend below a 1:1 projection from the heel of the wall. Alternatively, walls may be designed to accommodate structural loads from buildings or appurtenances.

7.4 Construction

The foundation construction considerations contained herein are presented as minimum preliminary recommendations from a soils engineering standpoint. Laboratory test results indicate the onsite soils' swell (expansion) potential is very low. During grading of the site, we recommend that no soil possessing an Expansion Index of more than 20 be placed within 18-inches of finish grade, if possible. As such, design parameters provided herein assume that finish grade soil materials will have a low expansion potential.

Recommendations by the project's design-structural engineer or architect, which may exceed the soils engineer's recommendations, should take precedence over the following minimum preliminary considerations. Final foundation design should be provided based on the expansion potential of the near surface soils encountered during grading.

7.5 Concrete Slab-on-Grade

Interior slabs can be grade supported by structural fill whose placement/compaction is documented by the project soils engineer/engineer geologist as recommended herein. The thickness of the slab should be in accordance with the structural engineer's design. However, based on geotechnical considerations, we recommend that concrete slabs be a minimum of 4-inches in thickness. Concrete slabs should be underlain by at least 2-inches of clean sand with a Sand Equivalent (SE) of at least 30. Where moisture condensation is undesirable, concrete slabs should be underlain with a moisture/vapor retarder consisting of a minimum 10-mil, visqueen membrane, with all laps sealed. The membrane should be underlain by a 2-inch layer of clean sand with the aforementioned sand layer placed over the visqueen to aid concrete curing. To reduce the potential for buildup of hydrostatic pressures, the free draining material under the slabs should have positive drainage with no low lying areas (i.e., depressions) created.

Floor slabs should be suitably reinforced and jointed (in accordance with Structural Engineer's recommendations) so that a small amount of independent movement can occur without causing damage. Based on the encountered geotechnical conditions, we recommend that floor slabs be reinforced with No. 4 bars spaced on 18-inch centers (each way)

The contractor should take the appropriate precautions to make sure that the reinforcement is placed and maintained within the middle one-third of the slab. Exterior slabs, such as walkways and driveways, can be adequately supported on documented structural fill that is at minimum 12-inches in thickness, and placed and compacted in accordance with the recommendations contained herein.

In preparation for slab or flatwork construction, the earthwork contractor should ensure that the onsite soils have been prepared as recommended and that field density tests have been performed to adequately document the relative compaction of the structural fill. Preparation of the native soils should be documented prior to placement of aggregate, structural components and/or fill.

Some minor cracking of slabs can be expected due to shrinkage. The potential for this slab cracking can be reduced by careful control of water/cement ratios in the concrete. The contractor should take appropriate curing precautions during the pouring of concrete in hot or windy weather to reduce the potential for cracking of slabs. We recommend that a slipsheet (or equivalent) be utilized if grouted fill, tile, or other crack-sensitive floor covering is planned directly on concrete slabs. All slabs should be designed in accordance with structural considerations.

All dedicated exterior flatwork should conform to standards provided by the governing agency including section composition, supporting material thickness and any requirements for reinforcing steel. Concrete mix proportions and construction techniques, including the addition of water and improper curing, can adversely affect the finished quality of the concrete and result in cracking and spalling of the slab. We recommend that all placement and curing be performed in accordance with procedures outlined by the American Concrete Institute and/or Portland Cement Association. Special consideration should be given to concrete placed and cured during hot or cold weather conditions. Proper control joints should be provided to reduce the potential for damage resulting from shrinkage.

Laboratory test results indicate that the upper soils contain soluble sulfate concentrations of 0.005 percent and chloride concentrations of 0.007 percent. The results of these analyses indicate a negligible corrosion potential to concrete. As such, Type II cement can be used in concrete elements that will be in contact with the upper soils.

8.0 PAVEMENT DESIGN RECOMMENDATIONS

Deleterious material, excessively wet or dry pockets, concentrated zones of oversized rock fragments, and any other unsuitable yielding materials encountered during grading should be removed. Once compacted fill and/or native soils are brought to the proposed pavement subgrade elevations, the subgrade should be proof-rolled in order to check for a uniform firm and unyielding surface. Representatives of the project geotechnical engineer should observe all grading and fill placement.

The upper 12-inches of pavement subgrade soils should be scarified; moisture conditioned to at least optimum moisture content and compacted to at least 95 percent of the laboratory standard (ASTM D1557). If loose or yielding materials are encountered during subgrade preparation, evaluation should be performed by EEI. Aggregate base materials should be properly prepared (i.e., processed and moisture conditioned) and compacted to at least 95 percent of the maximum dry density as determined by ASTM D1557. Aggregate base materials should conform to Caltrans specifications for Class 2 aggregate base.

All pavement section changes should be properly transitioned. Although not anticipated, if adverse conditions are encountered during the preparation of subgrade materials, special construction methods may need to be employed. A representative of the project geotechnical engineer should be present for the preparation of subgrade and aggregate base.

For design purposes we have assumed a Traffic Index (TI) of 4.5 for the proposed parking areas and 6.0 for drive areas at the subject property. These assumed TI's should be verified as necessary by the Civil Engineer or Traffic Engineer. For preliminary design purposes, we have conservatively assumed a preliminary R-Value of 20 for the materials likely to be exposed at subgrade. The modulus of subgrade reaction (K-Value) was estimated at 70 pounds per square inch per inch (psi/in) for an R-Value of 20 (Caltrans, 1974).

TABLE 3
Preliminary Pavement Design Recommendations

Traffic Index (TI)	Pavement Surface	Aggregate Base Material (1)
4.5 – Parking Stalls	3.0-inches Asphalt Concrete	6.0-inches
6.0 – Main Drive Areas	4.0-inches Asphalt Concrete	8.0-inches
Trash Area and Concrete Pavement	5.5-inches Portland Cement Concrete (2)	Optional

(1) R-Value of 78 for Caltrans Class 2 aggregate base
(2) Reinforcement and control joints placed in accordance with the structural engineer's requirements

The recommended pavement sections provided above are intended as a preliminary minimum guideline. If thinner or highly variable pavement sections are constructed, increased maintenance and repair could be expected. If the ADT (average daily traffic) or ADTT (average daily truck traffic) increases beyond that intended, as reflected by the assumed traffic index used for design, increased maintenance and repair could be required for the pavement section. Final pavement design should be verified by testing of soils exposed at subgrade after grading has been completed. Thicker pavement sections could result if R-Value testing indicates lower values.

9.0 DEVELOPMENT RECOMMENDATIONS

9.1 Landscape Maintenance and Planting

Water is known to decrease the physical strength of earth materials, significantly reducing stability by high moisture conditions. Surface drainage away from foundations and graded slopes should be maintained. Only the volume and frequency of irrigation necessary to sustain plant life should be applied.

Consideration should be given to selecting lightweight, deep rooted types of landscape vegetation which require low irrigation that are capable of surviving the local climate. From a soils engineering viewpoint, "leaching" of the onsite soils is not recommended for establishing landscaping. If landscape soils are processed for the addition of amendments, the processed soils should be re-compacted to at least 90 percent relative compaction (based on ASTM D1557).

9.2 Site Drainage

Positive site drainage should be maintained at all times. Drainage should not flow uncontrolled over slopes or the subject parcel. Runoff should be channeled away from slopes and structures and not allowed to pond and/or seep uncontrolled into the ground. Pad drainage should be directed toward an acceptable outlet. Although not required, roof gutters and down spouts may be considered to control roof drainage, discharging a minimum of 10 feet from the proposed structures, or into a subsurface drainage system. Consideration should be given to eliminating open bottom planters directly adjacent to proposed structures for a minimum distance of ten feet. As an alternative, closed-bottom type planters could be utilized, with a properly designed drain outlet placed in the bottom of the planter.

9.3 Stormwater Disposal Systems

EEI understands that current plans call for runoff generated from the facility to be disposed of in engineered subsurface features onsite.

9.3.1 Percolation Testing

During our subsurface exploration at the subject property, EEI conducted percolation testing in three widely separated locations (P1, P2 and P3) near the southern property boundary at the locations for proposed detention basins as shown on the conceptual site plan. Our testing was performed at an approximate depth of approximately 3 feet below the existing ground surface. A minimum 2-inch layer of ½-inch diameter crushed gravel was placed at the bottom of the excavation prior to testing. The approximate locations of our percolation test borings are provided on **Figure 3**.

Percolation testing was conducted by one of EEI's field geologists under the guidance of a Registered Engineering Geologist and Registered Civil Engineer with EEI. In general accordance with the County of Riverside guidelines for percolation testing, the percolation test locations were pre-soaked by pouring at least 5 gallons of water into the excavation. Testing was started after the hole was allowed to pre-soak for at least one hour. During testing, a minimum of 12-inches of water was placed in the excavation and the rate of the water drop was recorded at approximately 10 minute intervals. This procedure was repeated for the test hole until rates varied generally less than 10 percent for the test hole. We note that a soil profile's percolation rate is not the same as its infiltration rate. Therefore, the measured/calculated field percolation rate was converted to an estimated infiltration rate utilizing a reduction factor known as the Porchet method (Ritzema, 1974). Upon conclusion of testing, the perforated pipe was removed and the test excavation was backfilled. Results of percolation testing are presented in the following table, **Table 4**.

TABLE 4
Percolation Test Results

Test		Depth of Test (feet below existing grade)	Stabilized Percolation Rate (in/hr)	Infiltration Rate (in/hr)
P1		3	3.84	0.82
P2		3	3.60	0.50
P3		3	3.60	0.45

9.3.2 Summary of Findings

Based on the results of our percolation testing, it appears that a preliminary tested infiltration rate of 0.45-inches per hour can be used in preliminary design of subsurface stormwater retention/disposal devices at the property.

9.3.3 Structural Setback from Retention Devices

It is recommended that retention/disposal devices be situated at least three times their depth, or a minimum of 15 feet (whichever is greater), from the outside bottom edge of structural foundations. Structural foundations include (but are not limited to) buildings, loading docks, retaining walls, and screen walls.

9.4 Additional Site Improvements

Recommendations for additional grading, exterior concrete flatwork design and construction can be provided upon request. If in the future, additional property improvements are planned for the subject property, recommendations concerning the design and construction of improvements would be provided upon request.

9.5 Trenching

All temporary excavations for grading purposes and installation of underground utilities should be constructed in accordance with OSHA guidelines and local safety codes. Temporary excavations over 5 feet in height should be evaluated by the project engineer, and could require shoring, sloping, or a combination thereof. Temporary excavations within the onsite materials should be stable at 1:1 inclinations for cuts less than 10 feet in height.

Footing trench excavations for structures and walls should be observed and approved by a representative of the project soils engineer prior to placing reinforcement. Footing trench spoil and excess soils generated from utility trench excavations should be compacted to a minimum relative compaction of 90 percent (based on ASTM D1557) if not removed from the subject property. All excavations should conform to OSHA and local safety codes.

9.6 Utility Backfill

Fill around the pipe should be placed in accordance with details shown on the drawings, and should be placed in layers not to exceed 8-inches loose (unless otherwise approved by the geotechnical engineer) and compacted to at least 90 percent of the maximum dry density as determined in accordance with ASTM D1557 (Modified Proctor). The geotechnical engineer should approve all backfill material. Select material should be used when called for on the drawings, or when recommended by the geotechnical engineer. Care should be taken during backfill and compaction operations to maintain alignment and prevent damage to the joints. The backfill should be kept free from oversized material, chunks of highly plastic clay, or other objectionable material. Backfill soils should be non-expansive, non-corrosive, and compatible with native earth materials. Backfill materials and testing should be in accordance with the CBC (2013), and the requirements of the local governing jurisdiction.

Pipe backfill areas should be graded and maintained in such a condition that erosion or saturation will not damage the pipe bed or backfill. Flooding trench backfill is not recommended. Heavy equipment should not be operated over any pipe until it has been properly backfilled with a minimum of 2 to 3 feet of cover. The utility trench should be systematically backfilled to allow maximum time for natural settlement. Backfill should not occur over porous, wet, or spongy subgrade surfaces. Should these conditions exist, the areas should be removed, replaced and recompacted.

10.0 PLAN REVIEW

Once detailed site and grading plans are available, they should be submitted to this office for review and comment, to reduce the potential for discrepancies between plans and the preliminary recommendations presented herein. If conditions are found to differ substantially from those stated, appropriate recommendations would be provided. Additional field studies may be warranted.

11.0 LIMITATIONS

This Due Diligence Level Preliminary Geotechnical Evaluation has been conducted in accordance with generally accepted geotechnical engineering principles and practices. Findings provided herein have been derived in accordance with current standards of practice, and no warranty is expressed or implied. Standards of practice are subject to change with time. This Preliminary Evaluation report has been prepared for the sole use of Anderson Consulting Engineers, Inc. (Client), within a reasonable time from its authorization. Site conditions, land use (both onsite and offsite), or other factors may change as a result of man-made influences, and additional work may be required with the passage of time.

This Due Diligence Level Preliminary Geotechnical Evaluation should not be relied upon by other parties without the express written consent of EEI and the Client; therefore, any use or reliance upon this geotechnical evaluation by a party other than the Client should be solely at the risk of such third party and without legal recourse against EEI, its employees, officers, or directors, regardless of whether the action in which recovery of damages is brought or based upon contract, tort, statue, or otherwise. The Client has the responsibility to see that all parties to the project, including the designer, contractor, subcontractor, and building official, etc. are aware of this report in its complete form. This report contains information that may be used in the preparation of contract specifications; however, the report is not designed as a specification document, and may not contain sufficient information for use without additional assessment. EEI assumes no responsibility or liability for work or testing performed by others. In addition, this report may be subject to review by the controlling authorities.

APPENDIX C
EARTHWORK AND GRADING GUIDELINES

EEI
Geotechnical & Environmental Solutions

EARTHWORK AND GRADING GUIDELINES

GENERAL

These guidelines present general procedures and recommendations for earthwork and grading as required on the approved grading plans, including preparation of areas to be filled, placement of fill and installation of subdrains and excavations. The recommendations contained in the geotechnical report are applicable to each specific project, are part of the earthwork and grading guidelines and would supersede the provisions contained hereafter in the case of conflict. Observations and/or testing performed by the consultant during the course of grading may result in revised recommendations which could supersede these guidelines or the recommendations contained in the geotechnical report. Figures A through O are provided at the back of this appendix, exhibiting generalized cross sections relating to these guidelines.

The contractor is responsible for the satisfactory completion of all earthworks in accordance with provisions of the project plans and specifications. The project soil engineer and engineering geologist (geotechnical consultant) or their representatives should provide observation and testing services, and geotechnical consultation throughout the duration of the project.

EARTHWORK OBSERVATIONS AND TESTING

Geotechnical Consultant

Prior to the commencement of grading, a qualified geotechnical consultant (a soil engineer and engineering geologist) should be employed for the purpose of observing earthwork procedures and testing the fills for conformance with the recommendations of the geotechnical report, the approved grading plans, and applicable grading codes and ordinances.

The geotechnical consultant should provide testing and observation so that determination may be made that the work is being completed as specified. It is the responsibility of the contractor to assist the consultant and keep them aware of work schedules and predicted changes, so that the consultant may schedule their personnel accordingly.

All removals, prepared ground to receive fill, key excavations, and subdrains should be observed and documented by the project engineering geologist and/or soil engineer prior to placing any fill. It is the contractor's responsibility to notify the engineering geologist and soil engineer when such areas are ready for observation.

Laboratory and Field Tests

Maximum dry density tests to determine the degree of compaction should be performed in accordance with American Standard Testing Materials test method ASTM designation D-1557-78. Random field compaction tests should be performed in accordance with test method ASTM designations D-1556-82, D-2937 or D-2922 & D-3017, at intervals of approximately two (2) feet of fill height per 10,000 sq. ft. or every one thousand cubic yards of fill placed. These criteria would vary depending on the soil conditions and the size of the project. The location and frequency of testing would be at the discretion of the geotechnical consultant

Contractor's Responsibility

All clearing, site preparation, and earthwork performed on the project should be conducted by the contractor, with observation by geotechnical consultants and staged approval by the appropriate governing agencies. It is the contractor's responsibility to prepare the ground surface to receive the fill to the satisfaction of the soil engineer, and to place, spread, moisture condition, mix and compact the fill in accordance with the recommendations of the soil engineer. The contractor should also remove all major deleterious material considered unsatisfactory by the soil engineer.

It is the sole responsibility of the contractor to provide adequate equipment and methods to accomplish the earthwork in accordance with applicable grading guidelines, codes or agency ordinances, and approved grading plans. Sufficient watering apparatus and compaction equipment should be provided by the contractor with due consideration for the fill material, rate of placement, and climatic conditions. If, in the opinion of the geotechnical consultant, unsatisfactory conditions such as questionable weather, excessive oversized rock, deleterious material or insufficient support equipment are resulting in a quality of work that is not acceptable, the consultant will inform the contractor, and the contractor is expected to rectify the conditions, and if necessary, stop work until conditions are satisfactory.

The contractor will properly grade all surfaces to maintain good drainage and prevent ponding of water. The contractor will take action to control surface water and to prevent erosion control measures that have been installed.

SITE PREPARATION

All vegetation including brush, trees, thick grasses, organic debris, and other deleterious material should be removed and disposed of offsite, and must be concluded prior to placing fill. Existing fill, soil, alluvium, colluvium, or rock materials determined by the soil engineer or engineering geologist as unsuitable for structural in-place support should be removed prior to fill placement. Depending upon the soil conditions, these materials may be reused as compacted fills. Any materials incorporated as part of the compacted fills should be approved by the soil engineer.

Any underground structures such as cesspools, cisterns, mining shafts, tunnels, septic tanks, wells, pipelines, or other structures not located prior to grading are to be removed or treated in a manner recommended by the soil engineer. Soft, dry, spongy, highly fractured, or otherwise unsuitable ground extending to such a depth that surface processing cannot adequately improve the condition should be over excavated down to firm ground and approved by the soil engineer before compaction and filling operations continue. Over excavated and processed soils which have been properly mixed and moisture-conditioned should be recompacted to the minimum relative compaction as specified in these guidelines.

Existing ground which is determined to be satisfactory for support of the fills should be scarified to a minimum depth of six (6) inches, or as directed by the soil engineer. After the scarified ground is brought to optimum moisture (or greater) and mixed, the materials should be compacted as specified herein. If the scarified zone is greater than 6 inches in depth, it may be necessary to remove the excess and place the material in lifts restricted to six (6) inches in compacted thickness.

Existing grind which is not satisfactory to support compacted fill should be over excavated as required in the geotechnical report or by the onsite soils engineer and/or engineering geologists. Scarification, discing, or other acceptable form of mixing should continue until the soils are broken down and free of large fragments or clods, until the working surface is reasonably uniform and free from ruts, hollows, hummocks, or other uneven features which would inhibit compaction as described above.

Where fills are to be placed on ground with slopes steeper than 5:1 (horizontal to vertical) gradient, the ground should be benched. The lowest bench, which will act as a key, should be a minimum of 12 feet wide and should be at least two (2) feet deep into competent material, approved by the soil engineer and/or engineering geologist. In fill over cut slope conditions, the recommended minimum width of the lowest bench or key is at least 15 feet with the key excavated on competent material, as designated by the Geotechnical Consultant. As a general rule, unless superseded by the Soil Engineer, the minimum width of fill keys should be approximately equal to one-half (½) the height of the slope.

Standard benching is typically four feet (minimum) vertically, exposing competent material. Benching may be used to remove unsuitable materials, although it is understood that the vertical height of the bench may exceed four feet. Pre stripping may be considered for removal of unsuitable materials in excess of four feet in thickness.

All areas to receive fill, including processed areas, removal areas, and toe of fill benches should be observed and approved by the soil engineer and/or engineering geologist prior to placement of fill. Fills may then be properly placed and compacted until design grades are attained.

COMPACTED FILLS

Earth materials imported or excavated on the property may be utilized as fill provided that each soil type has been accepted by the soil engineer. These materials should be free of roots, tree branches, other organic matter or other deleterious materials. All unsuitable materials should be removed from the fill as directed by the soil engineer. Soils of poor gradation, undesirable expansion potential, or substandard strength characteristics may be designated unsuitable by the consultant and may require mixing with other earth materials to serve as a satisfactory fill material.

Fill materials generated from benching operations should be dispersed throughout the fill area. Benching operations should not result in the benched material being placed only within a single equipment width away from the fill/bedrock contact.

Oversized materials, defined as rock or other irreducible materials with a maximum size exceeding 12 inches in one dimension, should not be buried or placed in fills unless the location of materials and disposal methods are specifically approved by the soil engineer. Oversized material should be taken offsite or placed in accordance with recommendations of the soil engineer in areas designated as suitable for rock disposal. Oversized material should not be placed vertically within 10 feet of finish grade or horizontally within 20 feet of slope faces.

To facilitate trenching, rock should not be placed within the range of foundation excavations or future utilities unless specifically approved by the soil engineer and/or the representative developers.

If import fill material is required for grading, representative samples of the material should be analyzed in the laboratory by the soil engineer to determine its physical properties. If any material other than that previously analyzed is imported to the fill or encountered during grading, analysis of this material should be conducted by the soil engineer as soon as practical.

Fill material should be placed in areas prepared to receive fill in near-horizontal layers that should not exceed six (6) inches compacted in thickness. The soil engineer may approve thicker lifts if testing indicates the grading procedures are such that adequate compaction is being achieved. Each layer should be spread evenly and mixed to attain uniformity of material and moisture suitable for compaction.

Fill materials at moisture content less than optimum should be watered and mixed, and “wet” fill materials should be aerated by scarification, or should be mixed with drier material. Moisture conditioning and mixing of fill materials should continue until the fill materials have uniform moisture content at or above optimum moisture.

After each layer has been evenly spread, moisture-conditioned and mixed, it should be uniformly compacted to a minimum of 90 percent of maximum density as determined by ASTM test designation, D 1557-78, or as otherwise recommended by the soil engineer. Compaction equipment should be adequately sized and should be reliable to efficiently achieve the required degree of compaction.

Where tests indicate that the density of any layer of fill, or portion thereof, is below the required relative compaction or improper moisture content, the particular layer or portion will be reworked until the required density and/or moisture content has been attained. No additional fill will be placed in an area until the last placed lift of fill has been tested and found to meet the density and moisture requirements, and is approved by the soil engineer.

Compaction of slopes should be accomplished by over-building the outside edge a minimum of three (3) feet horizontally, and subsequently trimming back to the finish design slope configuration. Testing will be performed as the fill is horizontally placed to evaluate compaction as the fill core is being developed. Special efforts may be necessary to attain the specified compaction in the fill slope zone. Final slope shaping should be performed by trimming and removing loose materials with appropriate equipment. A final determination of fill slope compaction should be based on observation and/or testing of the finished slope face.

If an alternative to over-building and cutting back the compacted fill slope is selected, then additional efforts should be made to achieve the required compaction in the outer 10 feet of each lift of fill by undertaking the following:

- Equipment consisting of a heavy short-shanked sheepsfoot should be used to roll (horizontal) parallel to the slopes continuously as fill is placed. The sheepsfoot roller should also be used to roll perpendicular to the slopes, and extend out over the slope to provide adequate compaction to the face slope.

- Loose fill should not be spilled out over the face of the slope as each lift is compacted. Any loose fill spilled over a previously completed slope face should be trimmed off or be subject to re-rolling.

- Field compaction tests will be made in the outer two (2) to five (5) feet of the slope at two (2) to three (3) foot vertical intervals, subsequent to compaction operations.

- After completion of the slope, the slope face should be shaped with a small dozer and then re-rolled with a sheepsfoot to achieve compaction to near the slope face. Subsequent to testing to verify compaction, the slopes should be grid-rolled to achieve adequate compaction to the slope face. Final testing should be used to confirm compaction after grid rolling.

- Where testing indicates less than adequate compaction, the contractor will be responsible to process, moisture condition, mix and recompact the slope materials as necessary to achieve compaction. Additional testing should be performed to verify compaction.

- Erosion control and drainage devices should be designed by the project civil engineer in compliance with the ordinances of the controlling governmental agencies, and/or in accordance with the recommendations of the soil engineer or engineering geologist.

EXCAVATIONS

Excavations and cut slopes should be observed and mapped during grading by the engineering geologist. If directed by the engineering geologist, further excavations or over-excavation and refilling of cut areas should be performed. When fills over cut slopes are to be graded, the cut portion of the slope should be observed by the engineering geologist prior to placement of the overlying fill portion of the slope. The engineering geologist should observe all cut slopes and should be notified by the contractor when cut slopes are started.

If, during the course of grading, unanticipated adverse or potentially adverse geologic conditions are encountered, the engineering geologist and soil engineer should investigate, evaluate and make recommendations to mitigate (or limit) these conditions. The need for cut slope buttressing or stabilizing should be based on as-grading evaluations by the engineering geologist, whether anticipated previously or not.

Unless otherwise specified in soil and geological reports, no cut slopes should be excavated higher or steeper than that allowed by the ordinances of controlling governmental agencies. Additionally, short-term stability of temporary cut slopes is the contractor's responsibility.

Erosion control and drainage devices should be designed by the project civil engineer and should be constructed in compliance with the ordinances of the controlling governmental agencies, and/or in accordance with the recommendations of the soil engineer or engineering geologist.

SUBDRAIN INSTALLATION

Subdrains should be installed in accordance with the approved embedment material, alignment and details indicated by the geotechnical consultant. Subdrain locations or construction materials should not be changed or modified without approval of the geotechnical consultant. The soil engineer and/or engineering geologist may recommend and direct changes in subdrain line, grade and drain material in the field, pending exposed conditions. The location of constructed subdrains should be recorded by the project civil engineer.

COMPLETION

Consultation, observation and testing by the geotechnical consultant should be completed during grading operations in order to state an opinion that all cut and filled areas are graded in accordance with the approved project specifications.

After completion of grading and after the soil engineer and engineering geologist have finished their observations, final reports should be submitted subject to review by the controlling governmental agencies. No additional grading should be undertaken without prior notification of the soil engineer and/or engineering geologist.

All finished cut and fill slopes should be protected from erosion, including but not limited to planting in accordance with the plan design specifications and/or as recommended by a landscape architect. Such protection and/or planning should be undertaken as soon as possible after completion of grading.

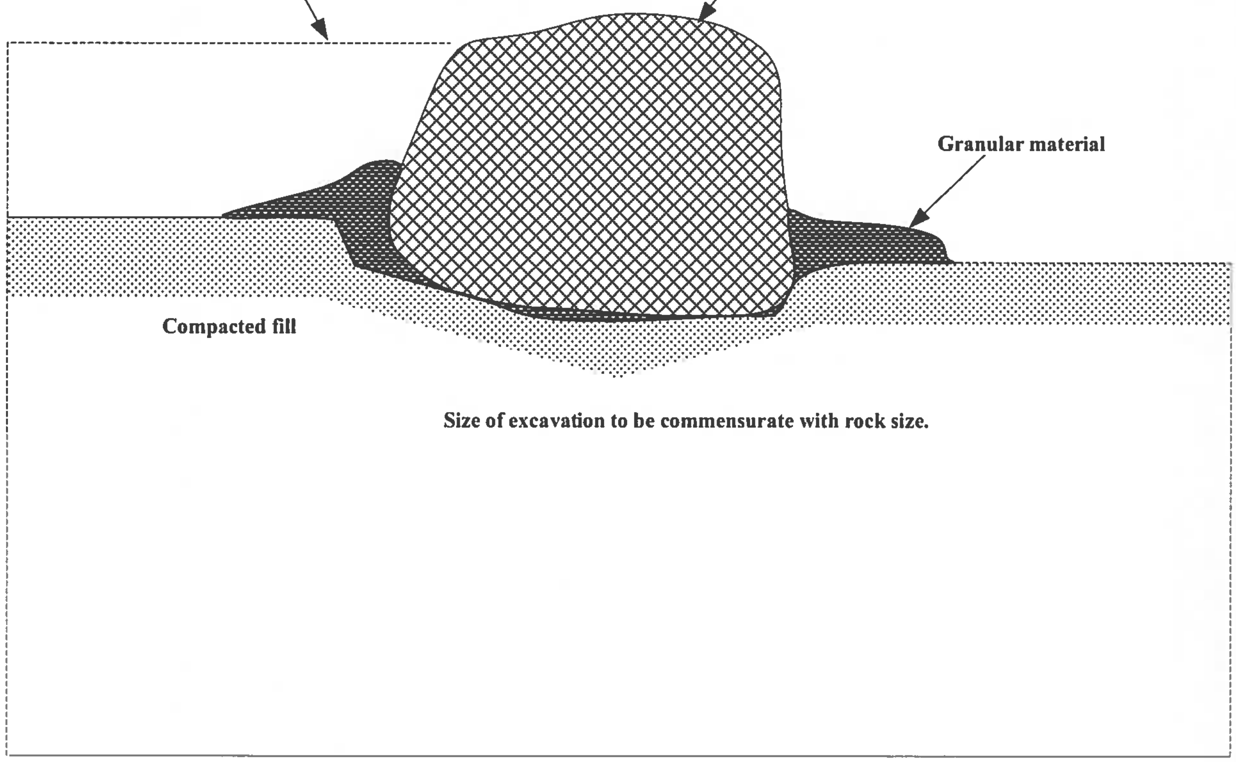
ROCK DISPOSAL PITS



Note:
(1) Large rock is defined as having a diameter larger than 3 feet in maximum size.
(2) Pit shall be excavated into compacted fill to a depth equal to half of the rock size.
(3) Granular soil shall be pushed into the pit and then flooded around the rock using a sheepsfoot to help with compaction.
(4) A minimum of 3 feet of compacted fill should be laid over each pit.
(5) Pits shall have at least 15 feet of separation between one another, horizontally.
(6) Pits shall be placed at least 20 feet from any fill slope.
(7) Pits shall be used only in deep fill areas.

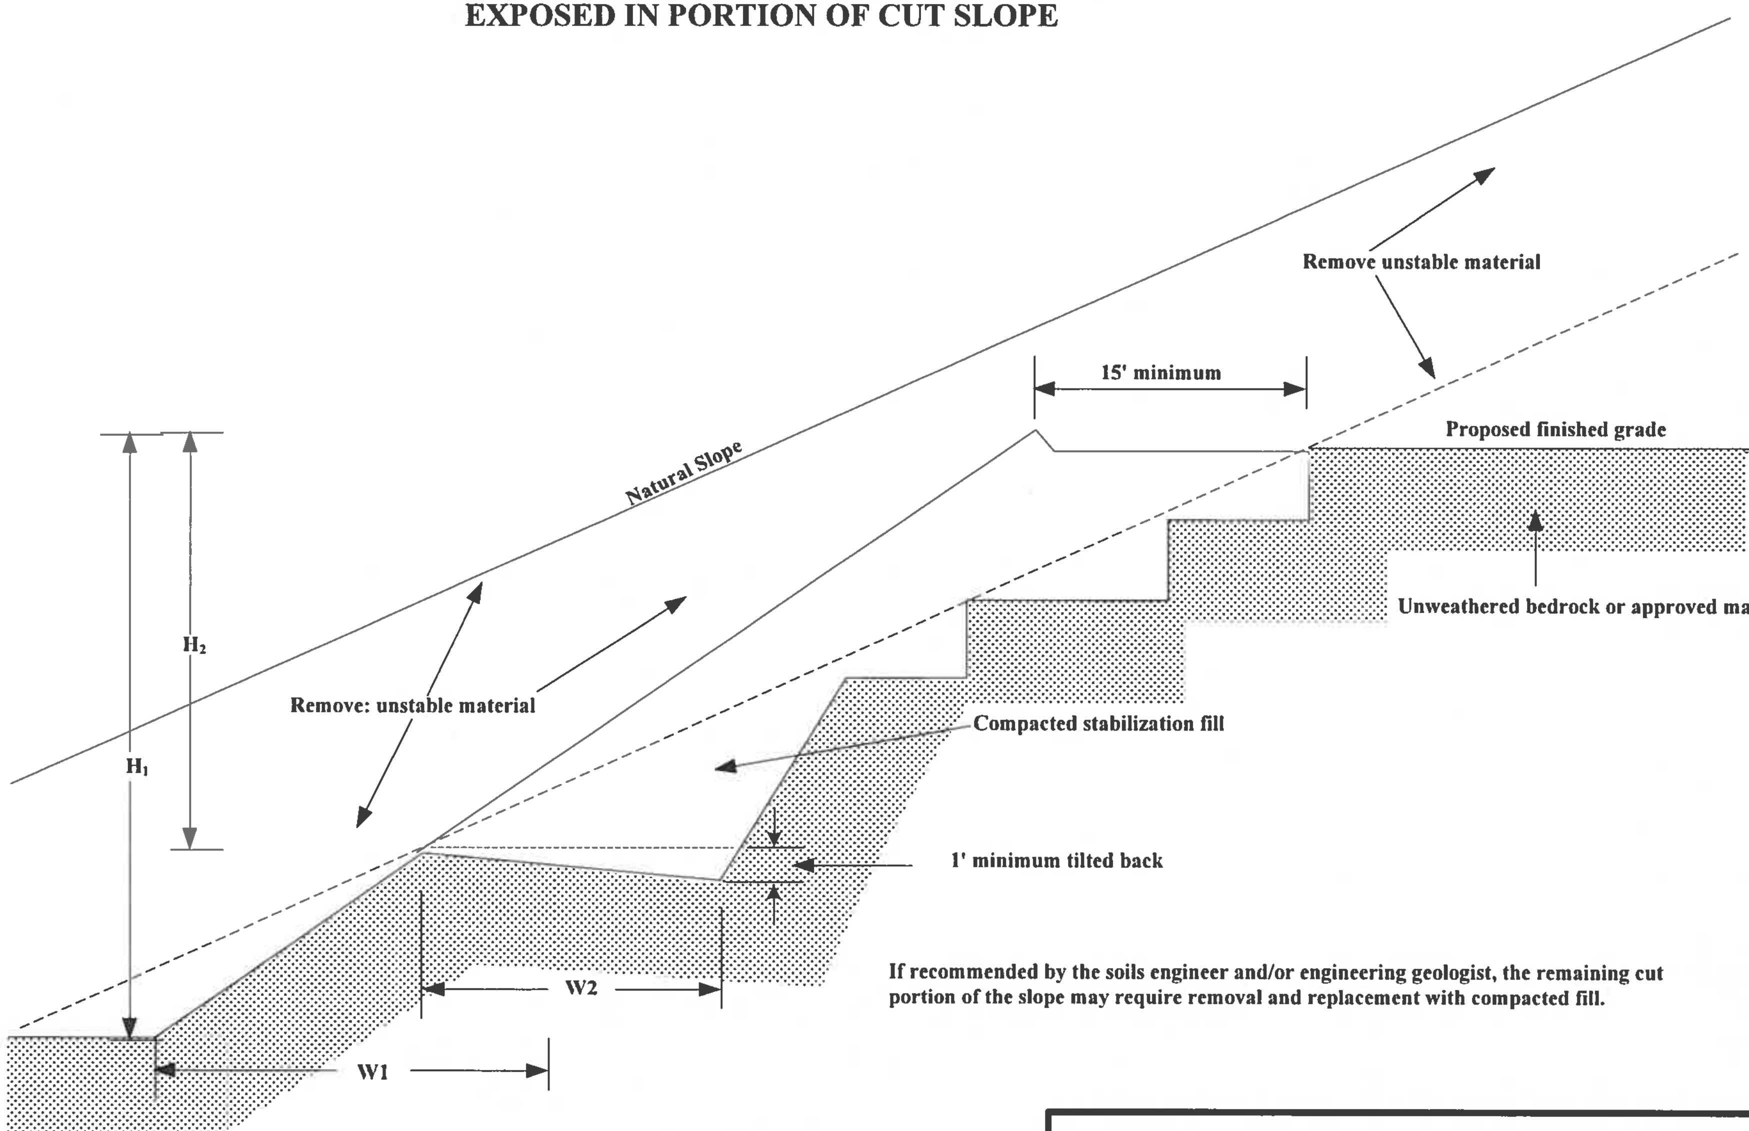
STABILIZATION FILL FOR UNSTABLE MATERIAL EXPOSED IN PORTION OF CUT SLOPE



If recommended by the soils engineer and/or engineering geologist, the remaining cut portion of the slope may require removal and replacement with compacted fill.

Note: (1) Subdrains are required only if specified by the soils engineer and/or engineering geologist.
(2) "W" shall be the equipment width (15') for slope heights less than 25 feet. For slopes greater than 25 feet "W" shall be determined by the project soils engineer and/or the engineering geologist. "W" shall never be less than H/2.

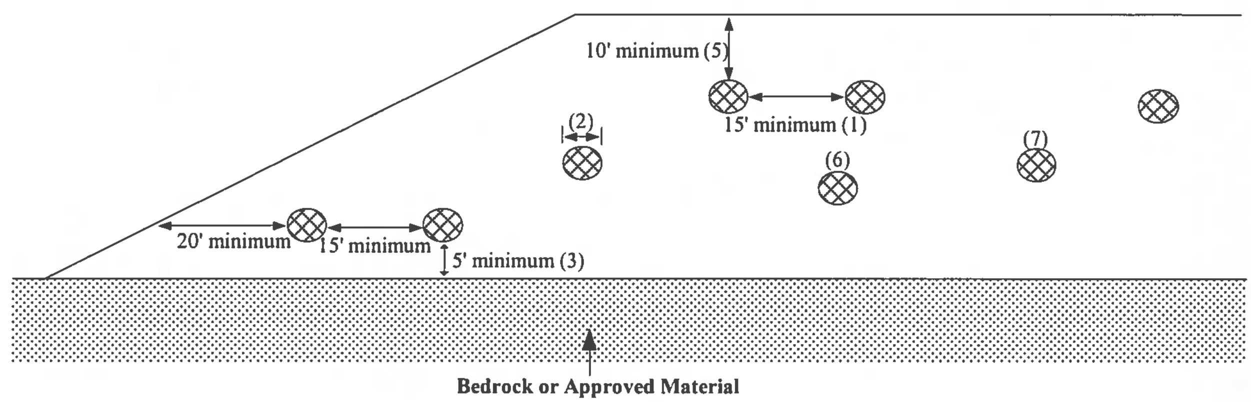
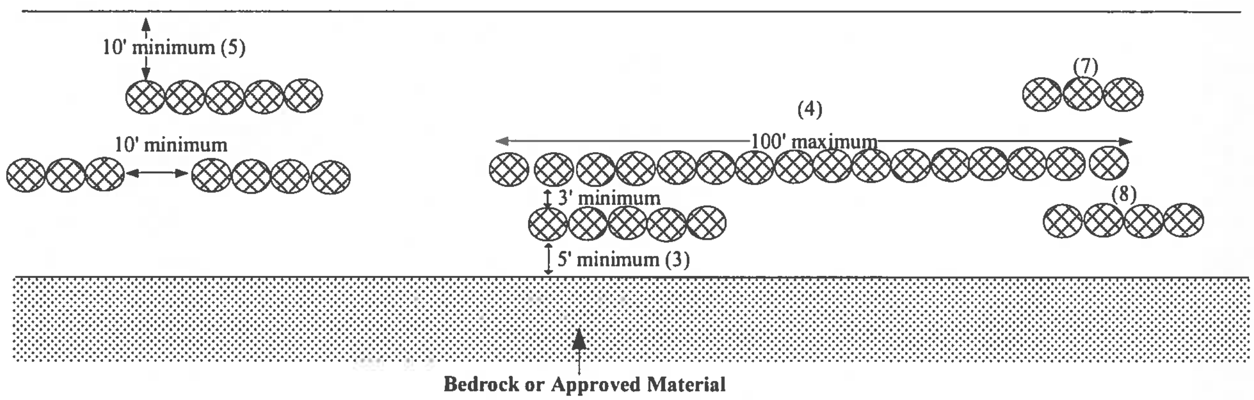
OVERSIZE ROCK DISPOSAL

View Normal to Slope Face



View Parallel to Slope Face



Note:
(1) One Equipment width or a minimum of 15 feet.
(2) Height and width may vary depending on rock size and type of equipment used. Length of windrow shall be no greater than 100 feet maximum.
(3) If approved by the soils engineer and/or engineering geologist.
(4) Orientation of windrows may vary but shall be as recommended by the soils engineer and/or engineering geologist. Unless recommended staggering of windrows is not necessary.
(5) Areas shall be cleared for utility trenches, foundations, and swimming pools.
(6) Voids in windrows shall be filled by flooding granular soil into place. Granular soil shall be any soil which has a unified soil classification system (Universal Building Code (UBC) 29-1). Designation of SM, SP, SW, GP, or GW.
(7) After fill between windrows is placed and compacted with the lift of fill covering windrow, windrow shall be proof rolled with a D-9 dozer or equivalent.
(8) Oversized rock is defined as larger than 12", and less than 4 feet in size.

Approximate Scale: 1" = 30'

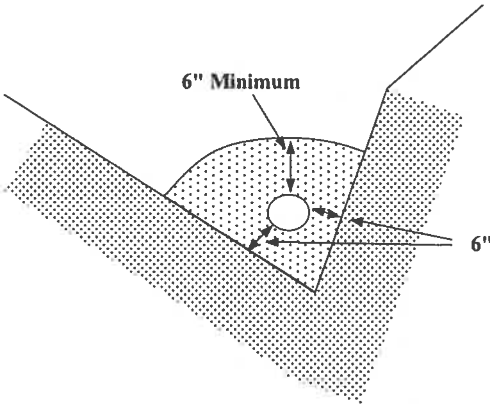
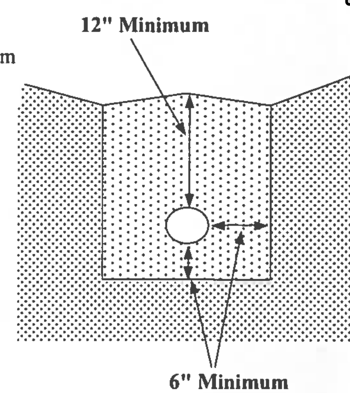
FIGURE M

CANYON SUBDRAIN ALTERNATE DETAILS

Alternate 1: Perforated Pipe and Filter Material



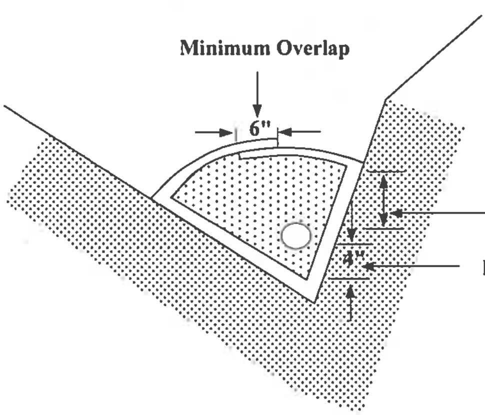
Filter material: Minimum volume of 9 feet^3/linear foot.
6" diameter ABS or PVC pipe or approved substitute with minimum 8 (¼" diameter) perforations per linear foot in bottom half of pipe.
ASTM D 2751, SDR 35 or ASTM D 1527, Schedule 40.
ASTM D 3034, SDR 35 or ASTM D 1785, Schedule 40.
For continuous run in excess of 500 feet use 8" diameter pipe.

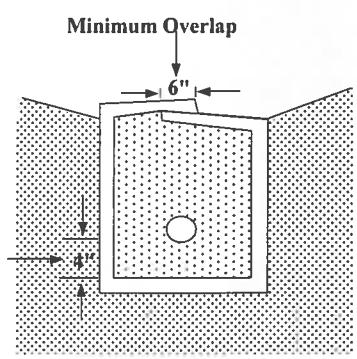


Filter Material

Sieve Size	Percent Passing
1"	100
¾"	90-100
3/8"	40-100
No. 4	25-40
No. 8	18-33
No. 30	5-15
No. 50	0-7
No. 200	0-3

Alternate 2: Perforated Pipe, Gravel and Filter Fabric





Gravel material 9 feet^3/linear foot.
Perforated pipe: see alternate 1.
Gravel: Clean ¾" rock or approved substitute.
Filter Fabric: Mirafi 140 or approved substitute.

Note: Figures not to scale

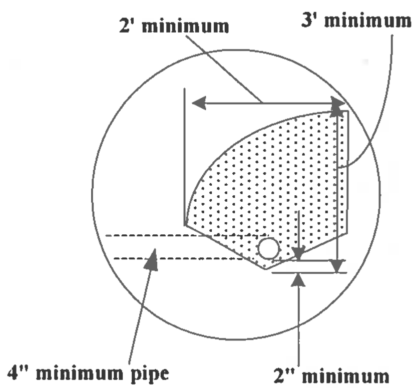
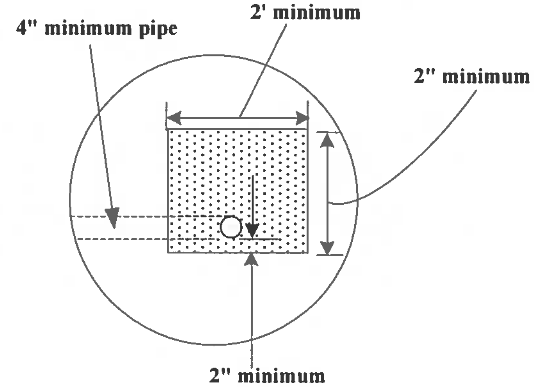
FIGURE N

TYPICAL STABILIZATION BUTTRESS SUBDRAIN DETAIL





Filter Material: Minimum of 5 ft^3/linear foot of pipe or 4 ft^3/linear foot of pipe when placed in square cut trench.

Alternative In Lieu Of Filter Material: Gravel may be encased in approved filter fabric. Filter fabric shall be mirafi 140 or equivalent. Filter fabric shall be lapped a minimum of 12" on all joints.

Minimum 4" Diameter Pipe: ABS-ASTM D-2751, SDR 35 or ASTM D-1527 schedule 40 PVC-ASTM D-3034, SDR 35 or ASTM D-1785 schedule 40 with a crushing strength of 1,000 pounds minimum, and a minimum of 8 uniformly spaced perforations per foot of pipe installed with perforations at bottom of pipe. Provide cap at upstream end of pipe. Slope at 2% to outlet pipe. Outlet pipe shall be connected to the subdrain pipe with tee or elbow.

Note:
(1) Trench for outlet pipes shall be backfilled with onsite soil.
(2) Backdrains and lateral drains shall be located at the elevation of every bench drain. First drain shall be located at the elevation just above the lower lot grade. Additional drains may be required at the discretion of the soils engineer and/or engineering geologist.

Filter Material – Shall be of the following specification or an approved equivalent:

Filter Material

Sieve Size	Percent Passing
1"	100
¾"	90-100
3/8"	40-100
No. 4	25-40
No. 8	18-33
No. 30	5-15
No. 50	0-7
No. 200	0-3

Gravel - Shall be of the following specification or an approved equivalent:

Filter Material

Sieve Size	Percent Passing
1½"	100
No. 4	50
No. 200	8

Sand equivalent: Minimum of 50

Appendix 8: Source Control

Pollutant Sources/Source Control Checklist

Appendix 9: O&M

Operation and Maintenance Plan and Documentation of Finance, Maintenance and Recording Mechanisms

Detailed Operations and Maintenance Plans will be provided during final engineering.

Appendix 10: Educational Materials

BMP Fact Sheets, Maintenance Guidelines and Other End-User BMP Information

Education Materials will be provided during final engineering
